So, you refuse, or cannot account for the energy? Energy is conserved
in every system, even pockets and when the units of volts in one case
are conveniently offered, your theory fails to balance the pockets.

Hi Hank,

As Ken offers, there are better readers than Outlook (the one you are
using). Mine is Agent, so I can answer for it. I used the free
version a dozen years ago, and bought the commercial version right
away. It allows for "regular expressions" in filters. With very few
of them, they wipe out a lot of trash. Of course, you have to be a
*nix wizard to know how to craft "regular expressions" but it also has
simpler rule structures that can cover a lot of ground too.

Yes you are right, some digital system use time diversity in turning their TX's on and off. 802.11/WiFi is one of them. When you have multiple nodes this is important. Your router situation isn't however relevant to the BPL question as that services doesnt cycle RF TX/RX. At the user level there are certainly multiple channels in use for BPL (both upload and download) but for all intents and purposes as an interfering source it "stays on".

My previous post said;

"The only situations where this will work well is if there are periods of no TXing of one station that can be exploited by the other"

Odd. Cecil has not named his "references" which is
quite unusual for he truly likes to name-drop: Ramo,
Whinnery, Hecht, IEEE, ...

You would be well served to google "reflection diagram"
or "bounce diagram" where you will find fine examples
of computing re-reflection using the source impedance
of generators modelled using the Thevenin equivalent
circuit. It is not particularly complicated, though
it can be tedious.

One of Cecil's common techniques is to declare any combination of perfect voltage source and resistance to be a "Thevenin equivalent", which he then claims relieves him of any obligation to consider the power supplied by the source or dissipated in the resistor.

Of course, that combination of components has no special properties or restrictions, and must conform to the same rules as any linear components. It is, in fact, an excellent choice for many examples and illustrations because of its bare simplicity. Only when a substitution is made for some other combination of linear components does the perfect voltage source and resistor become an "equivalent", and in that case you can correctly state that the power supplied by the perfect source and dissipated by the resistor aren't necessarily the same as for the circuit being replaced. But any analysis which isn't valid when driven by a perfect voltage source in series with a resistance (or current source in parallel with a resistance) is fundamentally flawed. Waving your hands and declaring it a "Thevenin equivalent" and therefore not subject to the rules all linear circuits must abide by is simply a way of saying your theory can't handle simple cases.

Moving on, my electrical circuits texts abound with examples in which some initial condition is assumed, then a source is "turned on" or connected with an imaginary switch at t = 0, and the transition from the initial state to steady or final state is studied -- exactly as I did in my analysis. The source is most often a perfect voltage or current source and, in the sections dealing with sine wave AC circuits, produces a sine wave. The assumption of an initial condition (usually, but not always, that all voltages and currents in the circuit are zero) is absolutely required when solving the fundamental integro-differential equations which result from circuits containing inductances and capacitances.

I'll be glad to give page references from Pearson & Maler and Van Valkenburg, but it's really not necessary since anyone having any electric circuits text can find abundant examples. It appears that some of the posters either never took a basic course in electrical circuits, or forgot some very fundamental principles which were taught. But used circuits texts can be purchased for a very modest price, so there's little excuse for remaining ignorant if a person is truly interested in learning about the topic. (There's also the Internet, but you have to be more careful in sorting out the good information from the bad, and this can be difficult if you're not already pretty well acquainted with the topic.) I'd really like it, too, since I'd be able to present an analysis now and then without having the most basic principles of linear circuit analysis questioned and debated.

I'm afraid that the fuss about the source is primarily a way to avoid confronting the facts, which are apparently disturbing to some of the imaginative alternative theories being promoted.

The SPICE simulation of the circuit I analyzed was, of course, a transient analysis. The source was a perfect voltage source which produced a sine wave beginning at t = 0 and continuously after that, just as in my analysis. For anyone having SPICE, here's the netlist:

```
* 360 degree transmission line with open end and voltage source,
* transient response showing runup

.TRAN .05 30

v0 1 0 sin(0 1 1hz)
tl1 1 0 2 0 td=1 z0=50
tl4 2 0 3 0 td=4 z0=50
rl 3 0 1meg

.PROBE
.END
```

TL_1_sec.gif is a plot of v(2), which is the junction of tl1 and tl4. TL_5_sec.gif is a plot of v(3), which is the open far end of the line. A plot of v(1) would of course show the source voltage, a constant 1 volt peak sine wave beginning at t = 0. As I mentioned, the 1 megohm terminating resistor rl is necessary to keep the version of SPICE I have from blowing up; it can be any value that's large enough to not have an

appreciable effect on the result.

```
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
-= the BBC, television and. radio -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
```

The first incident in June 1990 was when. a BBC newsreader made what seemed to be a reaction to something which had happened in my. home, and out of context. of what they were reading. My first reaction was disbelief; nothing of the sort had. ever happened before, the idea that such a thing could occur had not crossed. my mind, yet there was no doubt of what had just taken place. My disbelief eroded. as this recurred time after time. Besides the news, offenders included. shows such as Crimewatch (!), Newsnight, and "entertainment" shows. There seems to be very. little moral understanding among the people who make these programmes; they just. assume they will never be caught, so they carry on without. a thought for the illegality or amorality of what they do. The only time I ever. heard a word raised in doubt was by Paxman being. interviewed by someone else (I think by Clive Anderson). back in 1990; referring to the "watching" he said it troubled him, and when asked by the host. what you could do about it, replied "Well, you could just switch. it off" (meaning the surveillance monitor in the studio).. He clearly didn't let his doubts stand in the way of continued surreptitious. spying from his own or other people's shows, though.

Now you're convinced this is a troll, aren't you?. This story has been the subject. of much debate on the uk.* Usenet newsgroups for over a year, and some readers believe it. to be an invention (it has even been suggested that a group of psychology students. are responsible!), others think it symptomatic of a. derangement of the author, and a few give it credence. Quite a few people. do know part or all of the story already, so this text will fill in the gaps in their knowledge. For. the rest, what may persuade you of the third possibility is that some of the. incidents detailed are checkable against any archives of radio and TV. programmes that exist; that the incidents involve named people (even if. those hiding in the shadows have. not made their identity or affiliations evident), and those people may be persuaded to come out with the truth; and that. the campaign of harassment is continuing today both in the. UK and on the American continent, in a none-too-secret fashion; by. its nature the significant risk of. exposure increases with time.

On several occasions people. said to my face that harassment from the TV was happening. On the first day I worked in Oxford, I spent the evening. in the local pub with the. company's technical director Ian, and Phil, another employee. Ian made a few references to me and said to Phil,. as if in an aside, "Is he the bloke who's been on TV?" to. which Phil replied, "Yes, I

think. so".

I made a number of efforts to find the bugs,. without success; last year we employed. professional counter-surveillance people to scan for bugs (see later) again. without result. In autumn 1990 I disposed of my TV and watched virtually no television for the. next three years. But harassment from TV stations has gone on for over. six years and continues to this day. This is something that many people. obviously know is happening; yet the TV staff have. the morality of paedophiles, that because they're getting away with it they feel no. wrong.

Other people who were involved in the abuse. in 1990 were DJs on BBC radio stations, notably disc jockeys from Radio 1 and other. stations (see the following section). Again, since they. don't have sense in the first place they can't be. expect to have the moral sense not to be part of criminal harassment.

-= MI5: bugging and. counter-surveillance -=
-=-

PO: >Did you ever look for the bugs in your house ? If not, why not ? I. mean if
PO: >I thought that was happening. to me, I'd search the place from top to bottom,
PO: >I mean I live there I would know if anything. was out of place. If I was
PO: >really suspicious, I would call in one of those bug. detection teams which
PO: >have those machines that pick up the transmitted. radio waves. This
PO: >reminds me of. BUGS, that new programme on BBC1 on

That's exactly what we did. We went to a competent, professional. detective agency in London, paid them over 400 quid to debug our. house. They used scanner devices which go to over 1 GHz and would pick. up any nearby transmitter in that range, they also checked the. phones and found nothing... but if the tap was at the exchange,. then they wouldn't find anything, would. they?

CS: >Doesn't this suggest to you that. there are, in fact, no bugs to be found?

You can assume that they've done this sort. of thing to other people in more "serious" cases, where. they would know the targets would suspect the presence of electronic surveillance. So. they will have developed techniques and devices which are. not readily detectable either by visual inspection or by electronic means. What those techniques might be, I couldn't. guess.

In this case, the existence of. bugging devices was clear from the beginning, and they "rubbed it in" with what was said. by the boy on the coach. It was almost as if they. wanted counter-surveillance people to be called in, who they. knew would fail to detect the bugging devices, causing loss of credibility. to the other things I would have to say relating to the harassment.

I did all the things someone in my situation would do to try to. find the bugs.. In addition to calling in professional help using electronic counter-surveillance, I made a. close visual inspection of electrical equipment,. plus any points where audio or video surveillance devices might have been concealed. Of. course, I found nothing. Normal surveillance "mini-cameras" are quite noticeable and. require visible supporting circuitry. It seems to me the best. place to put a small video surveillance device would be additional to a piece of electronic equipment. such as a TV or video. It would be necessary. to physically break in to a property to fit such. a device.

```
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
-= Capital Radio. - Chris Tarrant -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
```

Capital Radio. DJs have been "in on it" from the start. One of the first things I heard in the summer of 1990 was from a Capital DJ who said,. "If he listens to Capital then he can't be all. bad" (supportive, you see. We're not bastards). Much of what came over the radio in 1990 is now. so far away the precise details have been obliterated by time.. No diary was kept of the details, and although archives if. they exist may give pointers, the ambiguity of. what broadcasters said would leave that open to re-interpretation.

In spring 1994, Chris Tarrant. on his Capital morning show made an aside to someone else in the. studio, about a person he didn't identify. He said, "You know this bloke? He. says we're trying to kill him. We should be done for attempted. manslaughter".

That mirrored something I had said. a day or two before. What Tarrant said was understood by the staff member. in the studio he was saying it to; they said, "Oh no,. don't say that" to Tarrant. If any archives exist of the morning show (probably unlikely) then it. could be found there; what he said was. so out of context that he would be very hard put to find an explanation. A couple of days later, someone at the site where I was working repeated. the remark although in a different way; they said there. had been people in a computer room when automatic. fire extinguishers went off and those people were "thinking of suing for. attempted manslaughter".

Finally, this isn't confined to the established radio stations. In. 1990 after I had listened to a pirate radio station in South. London for about half an hour, there was an. audible phone call in the background, followed by total silence for a few moments, then shrieks of. laughter. "So what are we supposed to say now? Deadly. torture? He's going to talk to us now, isn't he?", which meant that they. could hear what I would say in my room.

```
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=
-=. MI5: cost of the operation -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=

Here's what a couple of other people on. Usenet (uk.misc) had to say
regarding the cost of. running such an operation...

PO: >Have some sense, grow up and smell reality. What you are. talking about
PO: >would take loads of planning, tens of thousands of pounds and. lots of
PO: >people involved in the planning, execution and. maintenance of it. You
PO: >must have. a very high opinion of yourself to think you are worth it.

PM: >But why? And why you? Do you realize. how much it would cost to keep
PM:. >one person under continuous surveillance for five years? Think about
PM: >all. the man/hours. Say they _just_ allocated a two man team and a
PM: >supervisor. OK., Supervisor's salary, say, #30,000. a year. Two men,
PM: >#20,000 a year each. But they'd need to work in shifts --. so it would
PM:. >be six men at #20,000 (which with on-costs would work out at more like
PM: >#30,000 to the. employer.)
PM:. >
PM: >So, we're talking #30,000 x. 6. #180,000. plus say, #40,000 for the
PM: >supervisor. #220,000. Then you've got the. hardware involved. And
PM: >any transcription that needs doing. You don't. think the 'Big Boss'
PM:. >would listen to hours and hours of tapes, do you.
PM:. >
PM:. >So, all in all, you couldn't actually do the job for much less than
PM: >a quarter million a year. Over five years. What are you doing that. makes
PM: >it worth. the while of the state to spend over one and a quarter million
PM: >on. you?

Those are pretty. much the sort of calculations that went through my head
once I stopped to consider what. it must be costing them to run this
operation.. The partial answer is, there have been periods when the
intensity has. been greater, and times when little has happened. In fact,
for much of. 1993 and the first half of 1994, very little happened. Although
I don't think that was. for reasons of money - if they can tap into the
taxpayer they're not going to. be short of resources, are they?

The more. complete answer is in the enormity of what they're doing. Relative
to the cost. to British pride of seeing their country humiliated for the
persecution of their own citizens, isn't is worth the cost of. four or five
people to try to bring things to a close in. the manner they would wish? To
the government a million or two is quite honestly. nothing - if they can
convince. themselves of the necessity of what they're doing, resources will
```

not be the limiting. factor.

-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
-= how. and why did it start? -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-

The. harassment didn't start by itself, so someone must have been there at the outset to give it a firm push and set the "animals" after me. It. looks as if I was set. up in June 1990, and the timing indicates someone from university was. responsible.

>One thing which has been missing from. this discussion is this simple
>prognosis: that maybe he. is right and that, despite his admitted
>mental condition, there really is a campaign against him. organised by
>now-influential ex-students of his. university.

In May or. June 1990, Alan Freeman on Radio 1 read out a letter from someone who had. known me for a few years, who wrote of the one who "wore out his welcome with random precision" (from the. Pink Floyd song). Freeman went on to say to the writer "that's. a hell of a letter you wrote there". The indication. is strongly that people I had parted from soon before nursed a grudge against me and were trying to cause trouble for. me.

The suggestion is. that Freeman might have shown the letter to other people, and things could have snowballed from there. Right. from the start the real source. (security services presumed) didn't announce themselves as the origin, but let the "talkers", the radio DJs, believe that. they were the originators. Think about it; if you announce,. "we're MI5 and we have a campaign against this bloke" then people. might not go along with it; but if you say, "everyone else is. getting at this bloke because he 'deserves' it" then people will join in. with fewer qualms.

>Why would "they" wish to. assassinate your character?

It's the classic case of hitting a cripple to prove you're stronger.. Why would the security. services expend hundreds of thousands of pounds and more than six years of manpower to try to kill. a British citizen? Because they are motivated by people who knew me at university. and feel personal animosity; because they knew me to be emotionally. weak, and it is in the nature of bullies to prey on those. known to be weak; and because they can rely on the complicity of the. establishment, which the security services manipulate and derive funding from. This. is England's biggest humiliation today, and the British security services are intent on preventing. their humiliation. becoming reality by continuing their campaign of attempted murder to suppress the truth from. becoming public.

-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
-= how and why did it. start? -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-

The. harassment didn't start by itself, so someone must have been there at the outset to give it a firm push. and set the "animals" after me. It looks as if I was set up in June 1990, and the. timing indicates someone from university was. responsible.

>One thing which has. been missing from this discussion is this simple
>prognosis: that maybe he is right and that, despite his. admitted
>mental. condition, there really is a campaign against him organised by
>now-influential ex-students of his. university.

In May or June 1990, Alan Freeman on Radio. 1 read out a letter from someone who had known me for a few years, who wrote. of the one who "wore out his welcome with random precision" (from the Pink Floyd. song). Freeman went on to say to the writer "that's. a hell of a letter you wrote there". The indication is strongly that people I had parted from. soon before nursed a grudge against me and were trying. to cause trouble for me.

The suggestion is that Freeman might have. shown the letter to other people, and things could have snowballed from there. Right from the start the. real source. (security services presumed) didn't announce themselves as the origin, but. let the "talkers", the radio DJs, believe that they were the originators. Think about. it; if you announce, "we're MI5 and we have a campaign against this bloke" then people might not go along with it;. but if you. say, "everyone else is getting at this bloke because he 'deserves' it" then people will. join in with fewer qualms.

>Why would "they" wish. to assassinate your character?

It's the classic case of hitting a cripple. to prove you're stronger. Why would the security services expend hundreds of thousands of. pounds and more than six years. of manpower to try to kill a British citizen? Because they are motivated by people. who knew me at university and feel personal animosity; because they knew me to be emotionally weak, and. it is in the nature of bullies to prey on those. known to be weak; and because they can rely on the complicity of the. establishment, which the security services manipulate and derive funding from. This is England's. biggest humiliation today, and the British. security services are intent on preventing their humiliation. becoming reality by continuing their campaign of attempted murder to suppress the truth. from becoming public.

-=-=-=-=-=-=-=-=-=-=-=-=-
-= who knows. about it? =-
-=-=-=-=-=-=-=-=-=-=-=-=-

Many people know, both in the. establishment and media, and among the general public. Despite an absence of its target from the. UK for more than two. years, the echoes of paranoia can still be heard loud and clear from across the water. When it started in 1990,. the only people who knew were those. in BBC television who were spying on my home, and a few radio broadcasters. There were a few cases of public harassment, but. very little compared to the situation that developed a. couple of years later.

The list today includes BBC TV staff (newsreaders such as. Martyn Lewis, Michael Buerk, Nicholas Witchell), people from radio stations. such as Chris Tarrant of Capital and. Radio 1 DJs, people in the print media, but also many people in the general public. All united. in a conspiracy which breaks the laws which the UK does have regarding. harassment, and all completely uncaring for any semblance of. decency or elementary respect for individual. rights.

The. British police (obviously) do know the nature of the harassment and in all probability the identity of those behind it.. Some time ago I made a complaint to my local police station in London, without. positive result. The UK police are failing in their duty to see the law enforced in. not checking. the abuse.

actually,
Ive been using digital for some time (vhf/uhf). it has its pluses in some situations. However, I have found that under noisy RF conditions (such as leaky tv cable, etc) that mode won't work very well (its a true binary situation, either you are locked <have signal> or not <don't have signal>). once SNR drops below about 15 DBm, you are screwed. This is from lock hours of observation and troubleshooting.

At the time this article. was written I had believed for some time that columnists in the Times and other journalists. had been making references to my situation. Nothing unusual about this you may think, plenty of. people have the same sort of ideas and obviously the papers aren't writing. about them,. so why should my beliefs not be as false as those of others?

What. makes this article so extraordinary is that three or four days immediately. preceding its publication, I had a meeting with a friend, during the course of which we discussed. the media persecution, and in particular that by Times columnists. It seemed to me,. reading the article by Levin. in Saturday's paper, that he was describing in some detail his "artist's impression" of that meeting. Most. telling are the final sentences, when he writes, "The madman bursts into. tears, and swears it is all true. And it is." Although I did. not "burst into tears" (he seems to be using a bit of poetic licence. and exaggerating) I did try hard to convince my friend that it was. all true; and I am able to concur with Mr Levin, because, of course, it. is.

At the beginning of the piece Levin reveals a fear of being attacked. by the "irrational" subject of his story, saying. "I have no reason to believe that he is violent,. but he should certainly be approached with caution". This goes back to the xenophobic propaganda. of "defence" against a "threat" which was seen at the very beginning of the harassment. The. impression of a "madman running loose" who needs to. be controlled through an agency which assigns to itself the. mantle of the "police" is also one which had been expressed. elsewhere.

In the. final paragraph of this extract, his reference to Everyman's Library as. having "died a lingering and shameful death a decade or so ago" shows clearly what sort of conclusion they wish to their campaign. They. want a permanent solution, and as. they are prevented from achieving that solution directly, they waste. significant resources on methods which have been repeatedly shown. to be ineffective for such a purpose.

-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
-=. why won't the British police do their job and put a stop to it? -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
```

The. British police obviously do know what is taking place. Besides my interpretations of what individual. officers have said which forces that conclusion, it would be. inconceivable for them to be unaware of something on this. scale.

If they know, then they will know that the. abusers have broken laws in the UK and abroad. Recently the UK. introduced laws against electronic spying which carry a penalty of several years jail if. caught. If the police know illegal harassment. is taking place, and do nothing about it, then they are failing in. their responsibilities.

Last Easter (1995) I went into the. local police station in London and spoke to an officer about. the harassment against me. But I couldn't provide tangible. evidence; what people said, in many cases years ago, is beyond proof, and without something to support my statements I cannot. expect a police officer to take the complaint. seriously.

The current situation with regard to the police is not. one which allows a breakthrough in dealing with the. problem. On the one hand, most individual officers at a local police station may. not know about the ongoing assaults, so a complaint at that level will not yield results.. Yet the police as an organisation do know of the harassment, and they must. be aware that a complaint has been made at a police station. So it. is clearly their duty to take preventative action. against the continuing molestation, but because the criminals are operating on. behalf of a state agency, the police are not carrying. out their duty.

Okay so this is my last word on this useless tirade.

It appears now that like a politician or used car salesman you have made a incorrect statement (some may say lie) on how wonderful DV is at combating BPL, possibly to encourage amateurs to try it. Personally I don't condone this kind of behaviour, but maybe it has worked for you.

In my case I have to ask why I would even consider using DV for any reason. This is why I asked you to provide proof of how well it works. I was specific in my request, you waffled a reply. You failed to answer the burning question that was important to me, how well it performs compared to standard voice SSB close to the noise floor. You have to use such simple terms as "dB" when quantifying your answers. You went off on wild tangents, saying not a lot of unrelated things with no real answers. You didn't even admit to not knowing. This would have at least given you credibility.

Some may feel that the high S/N recovered audio is important and will no doubt try it because of that. Some just like to try new technology and others to discover that they need to do a better job flattening (amplitude and time delays) their TX filter passband to make multiple PSK carriers work well. I however would only be interested if by using some kind of codec magic it is possible to work further into the noise than a voice SSB signal. It is no doubt possible using more FEC and/or a narrower bandwidth, but you'd eventually get to the point where you would have to TX for a longer period than what the actual message is. This in itself might be interesting to do, but you might as well just use a text/keyboard mode.

Maybe you have a commercial interest in this mode? If you do you need a much better way of advertising it to those in the AR world that are technically oriented.

No equations. I expect that such equations would be more complex
than those describing the behaviour using superposition. Since
the existing equations and techniques for analysis are tractable
and produce accurate results, I am not motivated to develop an
alternate set with lower utility.

And yet the "no interaction" model, while accurately predicting
the behaviour has some weaknesses with explaining what is
happening. It is, I suggest, these weaknesses that help lead
some so far astray.

To illustrate some of these weaknesses, consider an example
where a step function from a Z0 matched generator is applied
to a transmission line open at the far end. Charge begins to
flow into the line. The ratio of the current to voltage on
the line is defined by the distributed inductance and
capacitance. The inductance is resisting the change in current
which causes a voltage to charge the capacitance. A voltage
step (call this V for later use) propagates down the line
at the speed of light. In front of this step, the voltage,
current and charge in the line is zero. After the step, the
capacitance is charged to the voltage and charge is flowing
in the inductance.

The step function eventually reaches the open end where
the current can no longer flow. The inductance insists
that the current continue until the capacitance at the
end of the line is charged to the voltage which will stop
the flow. This voltage is double the voltage of the step
function applied to the line (i.e 2*V). Once the
infinitesimal capacitance at the end of the line is
charged, the current now has to stop just a bit earlier
and this charges the inifinitesimal capacitance a bit

further from the end. So a step in the voltage propagates back along the line towards the source. In front of this step, current is still flowing. Behind the step, the current is zero and voltage is 2*V. The charge that is continuing to flow from the source is being used to charge the distributed capacitance of the line.

The voltage that is propagating backwards along the line has the value 2*V, but this can also be viewed as a step of voltage V added to the already present voltage V. The latter view is the one that aligns with the "no interaction" model; the total voltage on the line is the sum of the forward voltage V and the reverse voltage V or 2*V.

In this model, the step function has propagated to the end, been reflected and is now propagating backwards. Implicit in this description is that the step continues to flow to the end of the line and be reflected as the leading edge travels back to the source.

And this is the major weakness in the model. It claims the step function is still flowing in the portion of the line that has a voltage of 2*V and *zero* current.

Now without a doubt, when the voltages and currents of the forward and reverse step function are summed, the resulting totals are correct. But it seems to me that this is just applying the techniques of superposition. And when we do superposition on a basic circuit, we get the correct totals for the voltages and currents of the elements but we do not assign any particular meaning to the partial results.

A trivial example is connecting to 10 volt batteries in parallel through a .001 ohm resistor. The partial results show 10000 amps flowing in each direction in the resistor with a total of 0. But I do not think that anyone assigns significance to the 10000 amp intermediate result. Everyone does agree that the actual current in the resistor is zero.

The "no interaction" model, while just being superposition, seems to lend itself to having great significance applied to the intermediate results.

Partially this may be due to poor definitions. If the wave is defined as just being a voltage wave, then all is well.

But, for example, when looking at a solitary pulse, it is easy (and accurate) to view the wave as having more than just voltage. One can compute the charge, the current, the power, and the energy. But when two waves are simultaneously present, it is only legal to superpose the voltage and the current. But it is obvious that a solitary wave has voltage, current, power, etc. But when two waves are present it is not legal to.... etc., etc.
The "no interaction" model does not seem to resolve this conflict well, and some are lead astray.

And it was this conflict that lead me to look for other ways of thinking about the system.

Earlier you asked for an experiment. How about this one....

Take two step function generators, one at each end of a transmission line. Start a step from each end at the same time. When the steps collide in the middle, the steps can be viewed as passing each other without interaction, or reversing and propagating back to their respective sources. We can measure the current at the middle of the line and observe that it is always 0. Therefore the charge that is filling the capacitance and causing the voltage step which is propagating back towards each generator must be coming from the generator to which the step is propagatig because no charge is crossing the middle of the line.

Do you like it?

```
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
-= abuse in set-up situations and in. public -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
```

Strangers in the street. have recognized me on sight many times, and shown awareness. of the current thread of abuse. To give you one example, in 1992 I was seriously ill, and a manager at work somewhat. humorously said that "it wasn't. fair" that people were bullying me. A few days later, I attended for the first time a clinic in London as an outpatient,. and on my way out was accosted by someone. who asked if "they had paid my fare", with emphasis on the. word "fare". He repeated the word several times in this different context; that they should have paid my "fare", each time. emphasizing the word.

For two and a half years from the time their harassment started. until November. 1992 I refused to see a psychiatrist, because I reasoned that I was not. ill of my own action or fault, but through the stress caused by harassment, and that. a lessening of the illness would have to be consequent to a removal of its immediate cause, in other words a cessation. of harassment. I also reasoned that. since they were taunting me with jokes about mental illness, if I were. to seek treatment then the abusers would think that they had "won" and been proved "right". Remember,. the constant theme of any persecution is, "we must destroy you because. you're X", whether X is. a racial or other attribute. In this case the X was "we persecute. you because you have brain disease". The similarity of this logic to Nazi attitudes. to the mentally ill is striking.

The same. manager who'd said "it wasn't fair" asked me in winter 1992 why I didn't seek help from a. psychiatrist; was it, he asked, because "they would think they. had won" if I sought treatment? That was something I'd never said at work... again, taken separately it proves. nothing, but many such things over. a period of months proves conclusively that people in the company knew what was going on, and in quite. a lot of detail.

Usually harassment. in public lacks the level of finesse of "paying your fare". Most people's imagination does. not go beyond moronic parroting of the. current term of denigration. That is not surprising given the average level of the abusers; if they do not have. the intelligence to distinguish wrong from right then neither will they have the. capacity for anything other. than mindless repetition of a monosyllabic term calculated to fit into their. minds.

The first incidents of verbal assault. in public were in again in the summer of 1990, although they increased in frequency and venom with. time. In July

1990 the first public incident occurred on. a tube train on the Northern line. Two men and their girlfriends recognised me; the women sprang to. my defence,. saying "He looks perfectly normal, he doesn't look ill". Their boyfriends of course knew better, and followed the party line;. one of them made reference to. an "operation", apparently to work at the tube station but implicitly to a visit that I had. made to hospital a couple of weeks previously.

In August 1990 going home from college, soon after getting on. a tube train at Gloucester Road I was followed. by a group of four youths, who started a chant of abuse. That they were targeting me was confirmed by. other people in the carriage, one of whom asked the. other "who are they going on at, is it the bloke who just got on?" to which the second replied "yes,. I think so". I was tempted to reply, but as. in every other instance the abusers are enabled. in their cowardice by physically outnumbering the abused; any confrontation would result in my being beaten up, followed by. a complaint to the police that "he. attacked us", and of course he's ill, so he must have been imagining that we were getting at him. Shitty,. aren't they?

But the shittiness of the four youths on the tube train is. as nothing compared to the episode on the National Express. coach to Dover in the summer of 1992.. While going on holiday to the Continent I was verbally set upon by a couple. travelling sitting a few rows behind. The boy did the talking, his female companion contributing only a continuous. empty giggling noise. He spoke loudly to ensure other people. on the coach heard, always about "they" and "this bloke". but never naming either the abusers or the person he was talking about. He. said "they" had "found somebody from his school, and he was always really stressed. at school". They must have dug deep to find enemies there; perhaps someone who dropped. out of school, someone who didn't do too well later, who was jealous and. keen to get their own back? The boy also said "he was in. a bed and breakfast for only one night and they got him".. By a not unexpected coincidence I had been in a B&B in Oxford a week previously, which had been booked from work;. other things lead me to the conclusion that the company's. offices were bugged for most of the 2 1/2 years. that I was there, so "they" would have known a room in the. B&B had been booked. (But I'll bet "they" didn't tell the company's managers their offices were. bugged, did they?).

After a few minutes of this I went back. to where they were sitting and asked where. they were travelling. The boy named a village in France, and the. girl's giggling suddenly ceased; presumably it permeated to her brain cell what the purpose of the boy's abuse. was.

This and other set-up situations are obviously calculated to. provoke a direct confrontation. which would bring in the police, with the abusers claiming that they were the. ones attacked. Again in 1992, outside the house where I was living in Oxford I was physically. attacked by someone - not punched, just grabbed by the coat, with some verbals. thrown in for good measure. That was something the people at work. shouldn't have known about... but. soon after a couple of people were talking right in front of me about, "I heard he was attacked". The. UK police have a responsibility

for preventing assault occurring, but they do not seem. to take any interest in meeting that responsibility.. I suppose their attitude is that harassment does not come within their remit unless it involves physical assault,. and they will only become involved once that happens. That is of course. quite the wrong attitude for them to take, but. as I now understand, the police investigate only the crime they wish to investigate; if they. do not take your complaints seriously then there is nothing you can do to. make them take. action.

-=-
-= my response to the harassment. -=
-=-

My first reaction in. 1990/91 was to assume that if I broke contact then they would not be able to follow and would lose interest. So. I did the things that have been. suggested by other people; I sold my television, stopped listening to the radio and tried to withdraw away. from the sources of abuse as much as possible.. I reasoned that they must have more important things to. deal with and that normal people would simply leave me alone if it were made difficult for them. to continue their harassment.

I reckoned without the sheer vindictiveness of. the abusers. They did not let. up but instead "got to" people around me, mainly people at work, to do their dirty work for them. I went to see my GP, who refused to believe. what he was being told, and. refused to direct me on to anyone who could be of practical assistance.. It was not until three years had passed that the GP admitted the matter was outside his competence and. suggested going to the police.

In the summer of 1994. we called in counter-surveillance experts from a private detective agency. to sweep our house and telephone for bugging devices. They conducted a thorough search and found nothing; but. as noted above, since the existence of surveillance was. being forced in my face by the harassers, you would expect them to have. taken the possibility of a counter-surveillance sweep into account. when planning the type of devices to be. employed.

In Easter 1995 I made. a complaint to my local Police station in London, but the police have. not expressed any intention to do anything about the continuing harassment ("we're not saying. it's happening and we're not saying it isn't happening" were the. words used). I think the officer I spoke to at. Easter wasn't aware of it happening, although other members of the police. force obviously do know.

From April. 1995 until the present time the matter has been discussed in a lot of detail on the Usenet (Internet) "uk.misc" newsgroup. That. discussion has given birth to the article which you. are now reading. My hopes in posting to Usenet were. that wider publicizing would discourage the security services from continuing. their harassment, and "draw people out" into concurring with the truth of what was being said. Neither. of those have followed, but the. discussion has served a purpose in allowing this structured report to be. created.

A reference backing up your claim that a well-defined
source impedance can not be used to compute transient
reflections at the source would be entirely appropriate.

And you might find googling '"lattice diagram" reflection'
to assist in understanding the counter-claim.

-=. MI5: methods and tactics -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-

They deliberately set out to harass in a way. that would resemble the symptoms of schizophrenia, so that any report of. the harassment would be taken as indicating. mental illness and "treated" accordingly. They never show their own faces; they only work through. proxies, in the media, among the public, and by manipulating people in the workplace.. Since they do not declare their identity there. is no evidence to initiate legal action against the security services or anyone else.. The only people you can prosecute are the. proxies and they will deny knowledge of any conspiracy.

By repeatedly humiliating and abusing the. victim, they induced mental illness. This is the worst. form of human rights violation: making any statement of. the harassment appear to be symptomatic of the illness which they cause through the. harassment. That this can happen, and people collude by. silence, is absolutely horrifying.

From the beginning in June 1990 they set a. pattern of harassment which they have followed without. change for the last six years. They paint me as a "threat" to which people. must "react" (shades of Nazi persecution methods), while simultaneously. portraying their hate campaign on which they have spent over a million. pounds of taxpayers money as a "joke".

The. MI5 that breaks the law with the silent complicity of the police is the same agency that is. now seeking a role in the fight against crime. Perhaps the real joke is the proposed involvement in the. implementation of justice of an. organisation which commits criminal acts with secrecy and disinterest for. the legal process.

Everything can be understood within the context of
superposition and conservation of energy. No need
to invent any new laws of physics like EM waves
bouncing off each other in free space.

Any model that violates the laws of physics is fundamentally
flawed. Your model has EM energy sloshing around like water.
Your model has EM energy neither flowing into the source
nor being reflected. That is a violation of the conservation
of energy principle.

> The SPICE simulation of the circuit I analyzed was, of course, a
> transient analysis. The source was a perfect voltage source which

What is it that you think you have proved? That there
is no energy in reflected waves? That EM waves don't
move at the speed of light? That the conservation of
energy principle is invalid? What?

I made no such claim. My claim is that *your* source
is *NOT* well-defined and is just a result of your
hand-waving fantasies. When you stop refusing to
provide a schematic, we can discuss whether it is
well-defined or not.

Again, I freely admit that you can leap tall buildings

This disagrees with Roy, who assigns a -1 reflection coefficient when reflecting from a perfect voltage source.

The Norton or Thï¿½venin equivalent circuits seem capable of positive reflection coefficients. That is all that I am looking for.

Your search suggestion from a different posting '"lattice diagram" reflection'yields some examples that demonstrate positive reflection coefficients.

I must have missed something, because I can't understand why there is an insistence that a negative reflection coefficient must exist at the source for the 1/2 or 1 wavelength long transmission line fed at one end.

I don't think there is disagreement...
- perfect current source, infinite output impedance,
equivalent to open circuit, RC = 1
- perfect voltage source, zero output impedance,
equivalent to short circuit, RC = -1
- output impedance equal to Z0, RC = 0
- output impedance greater than Z0, RC > 0
- output impedance less than Z0, RC < 0

> The Norton or Thévenin equivalent circuits seem capable of positive
> reflection coefficients.

Either can be positive, negative, or zero depending
on the value of the output impedance compared to Z0.

> That is all that I am looking for.
>
> Your search suggestion from a different posting '"lattice diagram"

This would only be because the examples happened to use
output impedances greater than Z0.

> I must have missed something, because I can't understand why there is an
> insistence that a negative reflection coefficient must exist at the
> source for the 1/2 or 1 wavelength long transmission line fed at one end.

The reflection coefficient depends on the values of line
characteristic impedance (Z0) and the output impedance of the
source.

Recall that RC = (Z2-Z1)/(Z2+Z1)

For the reflected wave arriving back at the source,
Z1 is the characteristic impedance of the line (Z0)
and Z2 is the output impedance of the source.

Could you better describe how you determine that the source has a Z0
equal to the line Z0? I can guess that you use a Thï¿½venin equivalent
circuit and set the series resistor to Z0.

The power output of the Thï¿½venin equivalent circuit follows the load.
Therefore, when the load delivers power, the Thï¿½venin equivalent circuit
adsorbs power. Right?

Hi Keith,

It would seem we have either a Thevenin or a Norton source (again, the
ignored elephant in the living room of specifications). This would
have us step back to a Z0 in series with 2V or a Z0 in parallel with V
- it seems this would be a significant detail in the migration of what
follows:

>The step function eventually reaches the open end where
>the current can no longer flow. The inductance insists
>that the current continue until the capacitance at the
>end of the line is charged to the voltage which will stop
>the flow. This voltage is double the voltage of the step
>function applied to the line (i.e 2*V).

Fine (with omissions of the fine grain set-up)

However, what follows is so over edited as to be insensible:
>Once the
>infinitesimal capacitance at the end of the line is
>charged,
energy has reached the "end of the line" so to speak; and yet:
>the current now has to stop just a bit earlier
TIME is backing up? Are we at the edge of an event horizon?
>and this charges the inifinitesimal capacitance a bit
>further from the end.
BEYOND the end of the line? Just how long can this keep up?

Very strange stuff whose exclusion wouldn't impact the remainder:
>So a step in the voltage propagates
>back along the line towards the source. In front of this
>step, current is still flowing. Behind the step, the
behind the reflected step, rather?
>current is zero and voltage is 2*V.
Want to explain how you double the stored voltage in the distributed
capacitance of the line without current?
The definition of capacitance is explicitly found in the number of
electrons (charge or energy) on a surface; which in this case has not
changed.

>The charge that
>is continuing to flow from the source is being used
>to charge the distributed capacitance of the line.
It would appear now that charge is flowing again, but that there is a confusion as to where the flow comes from. Why would the source at less voltage provide current to flow into a cap that is rising in potential above it? Rolling electrons uphill would seem to be remarkable.

Returning to uncontroversial stuff:
>The voltage that is propagating backwards along the
>line has the value 2*V, but this can also be viewed as
>a step of voltage V added to the already present voltage
>V. The latter view is the one that aligns with the "no
>interaction" model; the total voltage on the line is
>the sum of the forward voltage V and the reverse
>voltage V or 2*V.
If this is the "latter view" then the former one (heavily edited above?) is troubling to say the least.

>In this model, the step function has propagated to the
>end, been reflected and is now propagating backwards.
>Implicit in this description is that the step continues
>to flow to the end of the line and be reflected as
>the leading edge travels back to the source.
This is a difficult read. You have two sentences. Is the second merely restating what was in the first, or describing a new condition (the reflection)?

>And this is the major weakness in the model.
Which model? The latter? or the former?
> It claims
>the step function is still flowing in the portion of
>the line that has a voltage of 2*V and *zero* current.
Does a step function flow? As for "zero" current, that never made sense in context here.

>Now without a doubt, when the voltages and currents
>of the forward and reverse step function are summed,
>the resulting totals are correct.
In this thread, that would be unique.

>But it seems to
>me that this is just applying the techniques of
>superposition. And when we do superposition on a
>basic circuit, we get the correct totals for the
>voltages and currents of the elements but we do
>not assign any particular meaning to the partial
>results.
Amen.

Unfortunately, more confusion:
>A trivial example is connecting to 10 volt batteries
>in parallel through a .001 ohm resistor.
Parallel has two outcomes, which one? "Through" a resistor to WHERE?
In series? In parallel?

Much to ambiguous.

>The partial
>results show 10000 amps flowing in each direction
>in the resistor with a total of 0.

This would suggest in parallel to the parallel batteries, but does not resolve the bucking parallel or aiding parallel battery connection possibilities. The 0 assignment does not follow from the description, mere as one of two possible solutions.

>But I do not
>think that anyone assigns significance to the 10000
>amp intermediate result. Everyone does agree that
>the actual current in the resistor is zero.

Actually, no. Bucking would have 0 Amperes. Aiding would have 20,000 Amperes.

However, by this forced march through the math, it appears there are two batteries in parallel; (series) bucking; with a parallel resistor.

>The "no interaction" model,
Is this the "latter" or former model?
>while just being
>superposition, seems to lend itself to having
>great significance applied to the intermediate
>results.
>
>Partially this may be due to poor definitions.
Certainly as I read it.
>If the
>wave is defined as just being a voltage wave, then
>all is well.
Still ambiguous.

And then deeper:
>But, for example, when looking at a solitary pulse,
>it is easy (and accurate) to view the wave as having
>more than just voltage. One can compute the charge,
>the current, the power, and the energy.
It would seem if you knew the charge, you already know the energy; but the power?

>But when
>two waves are simultaneously present, it is only
>legal to superpose the voltage and the current.
And illegal if only one is present? Odd distinction. Is there some

other method like superposition that demands to be used for this
instance?
>But it is obvious that a solitary wave has voltage,
>current, power, etc. But when two waves are present
>it is not legal to.... etc., etc.
>The "no interaction" model does not seem to resolve

I can only hope for clarity from this point on.

>Earlier you asked for an experiment. How about this
>one....
>
>Take two step function generators, one at each end
>of a transmission line. Start a step from each end
>at the same time. When the steps collide in the
>middle, the steps can be viewed as passing each
>other without interaction, or reversing and
>propagating back to their respective sources.

Why just that particular view?

>We
>can measure the current at the middle of the line
>and observe that it is always 0.

Is it? When?

If, for some infinitesimal line section, there is no current through
it, then there is no potential difference across it.

Hence, the when is some infinitesimal time before the waves of equal
potential meet - and no current flow forever after.

>Therefore the
>charge that is filling the capacitance and causing
>the voltage step which is propagating back towards
>each generator

How did that happen? No potential difference across an infinitesimal
line section, both sides at full potential (capacitors fully charged,
or charging at identical rates). Potentials on either side of the
infinitesimal line section are equal to each other and to the sources,
hence no potential differences anywhere, No potential differences, no
current flow, no charge change, no reflection, no more wave.

The last bit of induction went to filling the last capacitance element
with the last charge of current. Last gasp. No more gas. Nothing
left. Finis.

>must be coming from the generator
>to which the step is propagatig because no charge
>is crossing the middle of the line.

Would you please quote a reference that addresses
the subject of reflection coefficients from Thevenin
or Norton equivalent sources?

To the best of my knowledge, there is absolutely no
requirement that a Thevenin or Norton equivalent
circuit exhibit the same reflection coefficient
at the circuit it replaces.

The mere concept of a Thevenin equivalent circuit
absorbing power is contrary to the rules for the
use of a Thevenin equivalent circuit. No significance
can be automatically assigned to the power conditions
inside a Thevenin equivalent source.

Probably the simplest way is to put the entire source circuitry into a black box. Measure the terminal voltage with the box terminals open circuited, and the current with the terminals short circuited. The ratio of these is the source impedance. If you replace the box with a Thevenin or Norton equivalent, this will be the value of the equivalent circuit's impedance component (a resistor for most of our examples).

If the driving circuitry consists of a perfect voltage source in series with a resistance, the source Z will be the resistance; if it consists of a perfect current source in parallel with a resistance, the source Z will be the resistance. You can readily see that the open circuit V divided by the short circuit I of these two simple circuits equals the value of the resistance.

> The power output of the Thï¿½venin equivalent circuit follows the load.

Sorry, I don't understand this. Can you express it as an equation?

> Therefore, when the load delivers power, the Thï¿½venin equivalent circuit

Certainly, any energy leaving the transmission line must enter the circuitry to which it's connected. Is that what you mean?

This will do it. As will a Norton with the parallel
resistor set to Z0.

> The power output of the Thévenin equivalent circuit follows the load.
> Therefore, when the load delivers power, the Thévenin equivalent circuit
> adsorbs power. Right?

This apparently simple question has a very complicated
answer that depends on what precisely is meant by
"load delivers power" and "circuit absorbs power".

If by "load delivers power", you mean the reflected
wave, then this may or may not (depending on the
phase), mean that energy is transfered into the

generator.

If you mean that the time averaged product of the actual voltage and current at the generator terminals show a transfer of energy into the generator, then energy is indeed flowing into the generator.

If by "circuit absorbs power", you mean that there is an increase in the energy dissipated in the generator, this can not be ascertained without detailed knowledge of the internal arrangement of the generator and also depends the meaning of "load delivers power", discussed above.

This is obviously not true and easily illustrated using
a battery.

```
| |
Gnd--||---\/\/\/\/---+---(I)---||--Gnd
| 50 ohms |
12v 12v
```

Using a 12v source and current meter (I) to test the
impedance to ground from point '+', what does that
V/I impedance measure? Can you spell infinity?

The same principle holds true for an AC source when
phase is considered. Replace the 12v battery with
a 12vac source and test the impedance at '+' with
a phase-locked 12vac source. The measured V/I will
be infinite just as it is in the DC case.

It would certainly appear that the reflection coefficient
seen by the reflections changes depending upon the phase
of the reflections. In any case, the source Z is obviously
not what the reflections encounter.

> reflecting from a perfect voltage source.

It appears you're confusing perfect voltage and current sources.

A perfect voltage source has a zero impedance, so if it's connected to a transmission line with no series resistance, it presents a reflection coefficient of -1. A perfect current source has an infinite impedance, so if it's connected to a transmission line with no parallel resistance, the reflection coefficient is +1, as Keith says.

> The Norton or Thï¿½venin equivalent circuits seem capable of positive
> reflection coefficients. That is all that I am looking for.

Reflection coefficients are complex numbers, so they can't properly be described as "positive" or "negative" except in the special cases of +1 and -1. In all other cases, the can only be described by their magnitude and angle, or real and imaginary component. Under normal circumstances, reflection coefficients can have any magnitude from zero to one, and any angle. A Thevein equivalent, like the circuit it's replacing, can present any possible reflection coefficient. For example, a Thevenin equivalent circuit having an impedance of 19 - j172 (that is, the

equivalent consists of a perfect voltage source in series with a 19 ohm resistance and a capacitance of 172 ohms reactance) will present a reflection coefficient of about 0.8 - j0.5 to a 50 ohm transmission line. This is also true of a Norton equivalent consisting of a perfect current source shunted by an impedance of 19 - j172 ohms.

Of course, a voltage source and series impedance not acting as an equivalent for any other circuit can also be used to drive the line, and the source impedance will equal the impedance that's in series with the perfect source. Likewise a current source with a parallel impedance.

> . . .

> I must have missed something, because I can't understand why there is an
> insistence that a negative reflection coefficient must exist at the
> source for the 1/2 or 1 wavelength long transmission line fed at one end.

No one has insisted on that at all. As I've said, any reflection coefficient can exist at the source. It depends solely on the impedances of the transmission line and the source. Both Keith and I have given the equation describing the simple relationship, and you can find it also in many references. It was -1 for my example only because I used a perfect voltage source with no series impedance.

We have a black box. We use a 12vdc battery and a current
meter to measure the impedance of the black box. The
current meter reads zero when we connect the 12vdc battery
to the black box terminals. What is the impedance inside
the black box since test V/I = infinity?

What is actually in the black box is a very low source
impedance battery in series with a 50 ohm resistor.

This is what you are up against when reflections arrive
at your source. The ideal voltage source does *NOT* exhibit
zero ohms. Gary Coffman once likened it to spitting down
a fire hose.

If the reflections are in phase with the source voltage,
the source exhibits infinite ohms to the reflections and
of course, 100% re-reflection results. The reflection
coefficient encountered by the reflected waves is variable
and depends upon the relative phase between the source and
the reflections. The series resistor has very little effect
on the reflection coefficient.

There seems to be some confusion as to the terms "Thï¿½venin equivalent
>> circuit", "ideal voltage source", and how impedance follows these
sources.

Two sources we all have access to are these links:

Voltage source:
http://en.wikipedia.org/wiki/Voltage_source
Thï¿½venin equivalent circuit:
http://en.wikipedia.org/wiki/Th%C3%A9venin%27s_theorem

Three important observations about the ideal voltage source:

1. The voltage is maintained, no matter what current flows through the
source. Presumably, this would also mean that the voltage would be
maintained if a negative current flowed through the source. Thus, if we
set the voltage to 1 volt, the voltage would remain 1v even if we
supplied an infinite amount of power to the source.

2. The idea voltage source can ADSORB an infinite amount of power while maintaining voltage. In this capacity, it is like a variable resistor, capable of changing resistance to maintain a design voltage, no matter what current is supplied to it.

3. The idea voltage source has an infinite impedance at the design voltage, not a zero impedance as many have suggested. Zero internal resistance is assumed to reasonably allow the ideal voltage source to supply or adsorb current without changing voltage internally. It is not zero impedance with the result that voltage drops to zero if external power FLOWS INTO the ideal source.

Current flows into the ideal voltage source when the applied voltage exceeds the design voltage. At the point the current reverses, we have voltage/zero current, which is infinite impedance.

Two things to notice about the Thï¿½venin equivalent circuit:

1. It contains an ideal voltage source "IN SERIES" with a resistor. This has important implications when externally supplied voltage exceeds the design voltage. Any returning power would not only reverse the current flow in the ideal voltage source, it would develop voltage across the internal series resistor. The output Thevenin voltage would be the design voltage plus the voltage developed in the resistor.

2. The impedance of the Thevenin equivalent source would be infinite at the design voltage because a voltage will existed from the ideal source but current does not flow. This is true no matter what the design impedance is for the Thevenin source.

Please notice in the link about the Thevenin circuit, a reference to a "Thï¿½venin-equivalent resistance". This resistance uses the ideal voltage source set to zero. This appears to be the circuit that entered the discussion at some point, justifying a negative 1 reflection factor.

>> Therefore, when the load delivers power, the Thï¿½venin equivalent
>> circuit adsorbs power. Right?
>
> Certainly, any energy leaving the transmission line must enter the
> circuitry to which it's connected. Is that what you mean?
>
> Roy Lewallen, W7EL

If the rules found in the links are acceptable, I could agree that energy be allowed to enter the connected circuitry. I think we will find that the returning power from a reflected wave is either completely reflected with no change in energy, or adds to the voltage, thus increasing the current flow and power contained in the system.

I think you are on the right track, Roger. Another way of
saying it is: If the principles of superposition are used,
the superposition must necessarily be implemented. It appears
to me that the principles of superposition are being used but
the results of the ensuing necessary superposition are, for
some ulterior motive, being completely ignored.

When the superposition interference patterns between the source
waves and the reflected waves are taken into account, everything
becomes perfectly clear (including the deliberate obfuscations).

I think we will find it simpler than that.

I posted some links to descriptions of ideal voltage sources. After reading them, I am taking another look at how we define impedance from an ideal voltage source in a separate posting. You may wish to read the links, and hopefully, my posting.

Here are the links:

Voltage source:
http://en.wikipedia.org/wiki/Voltage_source

Thï¿½venin equivalent circuit:
http://en.wikipedia.org/wiki/Th%C3%A9venin%27s_theorem

As far as I can see, I've used the terms entirely consistently with the definitions and descriptions in the linked articles. If you can find any instance in which I haven't, please point it out so I can correct it.

> Three important observations about the ideal voltage source:
>
> 1. The voltage is maintained, no matter what current flows through the

Actually, the wikipedia article correctly states this explicitly.

> Thus, if we
> set the voltage to 1 volt, the voltage would remain 1v even if we
> supplied an infinite amount of power to the source.

You have to be very careful with using infinite amounts of anything because the underlying mathematics runs into problems. For example, look up "impulses" in any circuits text, and you'll find situations where a pulse has zero width and infinite height yet finite area. So let's just say the voltage stays at 1 volt if you apply any finite amount of current.

> 2. The idea voltage source can ADSORB an infinite amount of power while
> maintaining voltage.

Yes, that's correct.

> In this capacity, it is like a variable resistor,
> capable of changing resistance to maintain a design voltage, no matter
> what current is supplied to it.

No, that's not correct, unless you're willing to work with negative resistances. V/I is a negative number when you supply current to a voltage source. So it doesn't in any way act like a resistance, changing or not.

> 3. The idea voltage source has an infinite impedance at the design
> voltage, not a zero impedance as many have suggested.

No, that's not correct.

> Zero internal
> resistance is assumed to reasonably allow the ideal voltage source to
> supply or adsorb current without changing voltage internally.

Yes, that's correct.

> It is not
> zero impedance with the result that voltage drops to zero if external
> power FLOWS INTO the ideal source.

Sorry, I don't understand that statement. The voltage never changes, regardless of the current flowing in or out. Review the wikipedia article or any circuits text.

> Current flows into the ideal voltage source when the applied voltage
> exceeds the design voltage.

You can't "apply" a voltage to an ideal voltage source, except through an impedance. If you did, for example by connecting it to another voltage source of different value, the conditions defined for the voltage sources are contradictory and can't exist at the same time. If you do apply a voltage through an impedance, the current is simply the voltage across the impedance divided by the impedance.

> At the point the current reverses, we have
> voltage/zero current, which is infinite impedance.

It sounds like you're trying to calculate some sort of "instantaneous impedance". This isn't a generally accepted concept, and you'll have to develop a fairly complete set of rules and mathematics to cover it.

> Two things to notice about the Thï¿½venin equivalent circuit:
>
> 1. It contains an ideal voltage source "IN SERIES" with a resistor.
> This has important implications when externally supplied voltage exceeds
> the design voltage.

Not really. The current simply equals the voltage across the resistor divided by the resistance, in accordance with Ohm's law.

> Any returning power would not only reverse the
> current flow in the ideal voltage source, it would develop voltage

> across the internal series resistor. The output Thevenin voltage would
> be the design voltage plus the voltage developed in the resistor.

Your problem here, and I suspect elsewhere, is that you've embraced the idea that there are waves of flowing and reflecting power. Your otherwise reasoned questions and arguments are a good illustration into the traps this concept leads a person into. You're seeing that in order to support this mistaken concept, you have to reject some very fundamental principles of electrical circuit operation. So you end up with only two choices:

1. Re-write a great deal of fundamental circuit theory and reject the foundation which has consistently given demonstrably correct results for over a century, or
2. Realize that the flowing-power concept is flawed and abandon it.

The choice is yours.

> 2. The impedance of the Thevenin equivalent source would be infinite at
> the design voltage because a voltage will existed from the ideal source
> but current does not flow. This is true no matter what the design
> impedance is for the Thevenin source.

You're trying to define the impedance of a source as the ratio of its voltage to the current being drawn from it. That's not the impedance of the source, it's the impedance of the load. The two are not the same. The impedance of the source is its open circuit voltage divided by its short circuit current. Another way to determine the impedance of the source is to apply various loads and see how much the voltage drops. Any test you run will confirm that the ideal voltage source has a zero resistance, as my postings, the wikipedia article, or any circuits text tell you.

> Please notice in the link about the Thevenin circuit, a reference to a
> "Thï¿½venin-equivalent resistance".

This is the resistance component of the Thevenin equivalent circuit. It's equal to the resistance of the circuitry for which the Thevenin equivalent is being substituted.

> This resistance uses the ideal
> voltage source set to zero.

Can you explain this? There is no requirement that the source be set to zero in determining or using the Thevenin equivalent resistance.

> This appears to be the circuit that entered
> the discussion at some point, justifying a negative 1 reflection factor.

My analysis did not contain a Thevenin equivalent to any circuit. It contained only an ideal voltage source.

I have been down wrong tracks before! I sure hope this is the right
track. Thanks.

The principles of superposition are mathematically usable, not too hard,
and I think very revealing. Yes, if we use part of the model, we must
use it all the way. To do otherwise would be error, or worse.

You have been a supporter of this theory for a long time.

>a rotor? They both are still omnidirectional any way right? Why would
>this benefit?

Stacking two omni-vertical antennas one above another can increase the gain towards the horizon (where you tend to want it) at the expense of gain at higher and lower elevation angles (where you usually don't care very much). To get this improvement, though, it's necessary to use a phasing harness which combines the signals properly in-phase and preserves the correct impedance... and this is much more easily said than done for a multi-band antenna! Do it wrongly, and you could easily end up with a system that had *less* gain towards the horizon than a single antenna would, at much greater cost.

Turning such a stacked pair (or even a single such antenna) via a rotor seems nonsensical to me in most cases. The only case in which it could make a very small amount of sense, would be if the antenna (or stacked pair) is side-mounted on a mast or tower. The presence of the mast or tower will cause the pattern to be somewhat less than truly omnidirectional... there will probably be a partial null (a "weak spot" in the pattern) in the direction of the tower. Rotating a side-mounted stacked pair so it was on the opposite side of the mast would change the "sweet spot".

The improvement in coverage would probably be small (from either stacking, or rotating). Seems like a lot of expense to go to for a small gain. From the manufacturer's point of view, it's probably a great idea... they sell two antennas instead of one :-)

>on the frequencies it uses.

Correct, 802.11 access-point-to-client connections use time-division
multiplexing, coordinated by the access point. No two radios are
transmitting at the same time. If you start doing active transfers
down to 2, 3, 4, etc. of those client computers at the same time,
you can watch the bandwidth that each of them gets start to degrade.
Even if all of the clients report that they're seeing a strong signal
and are using a full-speed modulation, none of them will get more than
a fraction of the total bandwidth.

It'll get even nastier if you try to run two or more access points
(with their sets of clients) on channel 6, with overlapping coverage
zones. Each group will see the others' transmissions as noise,
resulting in poorer coverage, an increased rate of packet
retransmissions, and (likely) a fallback to a slower data-modulation
rate.

Digital modulations are useful. They are *not* a panacea for noise
and interference. When you throw together WiFi, Bluetooth, Zigbee,
frequency-hopping cordless phones, and the odd microwave oven in the
same band, the speed and reliability of wireless connections can go to
hell abruptly and thoroughly.

Roy, your problem is that you have embraced the idea that
reflected waves contain zero energy such that zero reflected
energy can be measured as zero reflected power passing a
measurement point. However, zero energy waves are impossible!!!

> 2. Realize that the flowing-power concept is flawed and abandon it.

Why don't you realize that reflected waves of zero energy
are impossible?

> Can you explain this? There is no requirement that the source be set to
> zero in determining or using the Thevenin equivalent resistance.

It is a requirement of the superposition principle that the
source voltage be set to zero for determining the voltage and
current due only to the reflected wave. I'm surprised you
are trying to sweep that fact under the rug.

> My analysis did not contain a Thevenin equivalent to any circuit. It
> contained only an ideal voltage source.

An ideal voltage source plus a series resistor *IS* a Thevenin
equivalent circuit. Nice try at obfuscation.

> You're building a logical argument from a flawed premise.

Nobody's premise is more flawed than yours.

You are only performing 1/2 of the pre-superposition phase.
Everything can be explained if you actually go through with
the superposition of which you are so afraid.

Roy and Keith don't seem to realize that the zero source impedance for the ideal voltage source is only when the source is turned off for purposes of superposition. They conveniently avoid turning the source voltage on to complete the other half of the superposition process. When the source signal and the reflected wave are superposed at the series source resistor, where the energy goes becomes obvious. Total destructive interference in the source results in total constructive interference toward the load. See below.

> You have been a supporter of this theory for a long time.

Yes, I have. I am a supporter of the principles and laws of physics. Others believe they can violate the principle of conservation of energy anytime they choose because the principle of conservation of energy cannot be violated - go figure.

Roger, I have explained all of this before. If you are capable of understanding it, I take my hat off to you. Here's what happens in that ideal voltage source using the rules of superposition.

1. With the reflected voltage set to zero, the source current is calculated which results in power in the source resistor. Psource = Isource^2*Rsource

2. With the source voltage set to zero, the reflected current is calculated which results in power in the source resistor. Pref = Iref^2*Rsource

Now superpose the two events. The resultant power equation is: Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(A) where 'A' is the angle between the source current and the reflected current. Note this is NOT power superposition. It is the common irradiance (power density) equation from the field of optics which has been in use in optical physics for a couple of centuries so it has withstood the test of time.

For the voltage source looking into a 1/2WL open
circuit stub, angle 'A' is 180 degrees. Therefore
the total power in the source resistor is:

Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(180) or

Ptot = Ps + Pr - 2*SQRT(Ps*Pr) = 0

Ptot in the source resistor is zero watts but we
already knew that. What is important is that the
last term in that equation above is known as the
"interference term". When it is negative, it indicates
destructive interference. When Ptot = 0, we have
"total destructive interference" as defined by
Hecht in "Optics", 4th edition, page 388.

Whatever the magnitude of the destructive interference
term, an equal magnitude of constructive interference
must occur in a different direction in order to
satisfy the conservation of energy principle. Thus
we can say with certainty that the energy in the
reflected wave has been 100% re-reflected by the
source. The actual reflection coefficient of the
source in the example is |1.0| even when the source
resistor equals the Z0 of the transmission line.
I have been explaining all of this for about 5 years
now. Instead of attempting to understand these relatively
simple laws of physics from the field of optics, Roy
ploinked me. Hopefully, you will understand.

All of this is explained in my three year old Worldradio
energy article on my web page.

I do not think so. Regardless of the output impedance of the
generator, the step impresses some voltage V which begins
to propagate down the line. Since the experiment ends before
the reflection returns to the generator, the impedance
of the generator is irrelevant.

> TIME is backing up?

Ah. The challenge of written precisely. Consider the
generator to be on the left end of the line and the open
to be at the right end. When the capacitance at the right
end charges to 2 * V, the current now has to stop a little
bit more to the left.

> Are we at the edge of an event horizon?>and this charges the inifinitesimal capacitance a bit
> >further from the end.
>
> BEYOND the end of the line? Just how long can this keep up?

Again, the poor writing meant a bit further to left
from the end.

The energy formerly present in the inductance of the line
has been transferred to the capacitance.

> The definition of capacitance is explicitly found in the number of
> electrons (charge or energy) on a surface; which in this case has not
> changed.>The charge that

Using the new reference scheme, charge to the left
of the leftward propagating step continues to flow,
while charge to the right has stopped flowing.

> Why would the source at
> less voltage provide current to flow into a cap that is rising in
> potential above it?

The beauty of inductance. You get extra voltage when
you try to stop the flow.

> Rolling electrons uphill would seem to be
> remarkable.

Well yes, but they don't roll for long. And you don't
get more out than you put in. Pity. Or I could be quite rich.

>
> If this is the "latter view" then the former one (heavily edited
> above?) is troubling to say the least.

Challenges with the referent.
The former view is that a voltage of 2*V is propagating
back along the line. The latter view is that it is a
step of V above the already present V.

> >In this model, the step function has propagated to the

> merely restating what was in the first, or describing a new condition
> (the reflection)?

Agreed. What is a good word to describe the constant
voltage that follows the actual step change in
voltage? The "tread" perhaps?

"The tread continues to flow to the end of the line
and be reflected as the leading edge travels back to
the source."

I am not sure that that is any clearer.

> >And this is the major weakness in the model.
>

The "no interaction" model.

> The latter? or the former?> It claims
> >the step function is still flowing in the portion of

Perhaps the "tread"? But then should the step change
be called the "riser"?

> As for "zero" current, that never made
> sense in context here.

Somewhat clarified, I hope. But for clarity, the
current to the right of the leftward propagating
step is zero.

It happens without effort because the output impedance
of the Norton/Thevenin equivalent circuit is the same
as the circuit it replaces, otherwise it is not an
equivalent.

Re: "Ken
You have a direct line with Yahoo who aids and abets kb9...
If they don't care who they support then drop them.
Yahoo is probably happy with what their customers are doing
on the net. Ofcourse if MI5 can't get the other guy write
a letter to the CIA they would know what to do."

Art, I suspect the problem with MI5 is the drastic reduction in funding due to the end of the cold war. One would think with the guy going to Canada and Florida the MI6 could step in and make a good hit without the assistance of the CIA. The CIA today is rather useless, not being able to even estimate Iranian WMD capability much less using electromagnetism to effect mind control :-)

More seriously, my theory is that this MI5 is a prank that started at the psychology department of some UK university and the students carry it on as a tradition year after year. They seem very adept at making themselves unflilterable.

If MI5 could only stop him from coming back they would have 100% of my support ;-)

Cecil,

Still up to your tricks? I ask for reference on a scalar quantity, and
you respond with some stuff about vectors.
```

If you want to continue to misinterpret the experts and believe that power, energy, or whatever flows in opposite directions at a single point at the same time, go right ahead. I suppose such beliefs expounded on RRAA are quite harmless in the grand scheme of world affairs.

For future reference, however, just remember: Fields first, then power or energy. That's the way superposition really works.

(By the way, I am not the one who made the point about power vs. energy. That must have been someone else.)

Recall that impedance is the slope and to obtain
the slope you need to do two measurements. Only if
the entity is completely passive can you make only
one measurement because in that case the line passes
through the origin which is the implicit other
measurement.

With two measurements you will obtain the correct
impedance.

> Thévenin equivalent circuit:http://en.wikipedia.org/wiki/Th%C3%A9venin%27s_theorem

I don't disagree with anything I read there.

But you may not quite have the concept of impedance
correct.

The impedance of the Thevenin/Norton equivalent source
is not V/I but rather the slope of the line representing
the relationship of the voltage to the current.
When there is a source present, this

line does not pass through the origin. Only for
passive components does this line pass through
the origin in which case it becomes V/I.

Because the voltage to current plot for an ideal
voltage source is horizontal, the slope is 0 and hence
so is the impedance. For an ideal current source
the slope is vertical and the impedance is infinite.

Hoping this helps clarify....

Can you make this all work for a pulse, or a step
function?

How do you compute
Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(A)
for a pulse or a step?

Or is your approach limited to sinusoids?

Well, I would like to think I could understand it, but maybe something is
wrong like Roy suggests. I think it is all falling into place, but our
readers are not all in agreement.

Could I ask a couple of questions to make sure I am understanding your
preconditions?

Is this a Thevenin source? If so, what is the internal resistor set to in
terms of Z0?

OK. A few reactions.

1. To add the total power of each wave and then also add the power
reduction of the phase relationship, would be creating power unless the
cos(A) is negative. Something seems wrong here, probably my understanding.

2. The two voltages should be equal, therfore the power delivered by each
to the source resister would be equal.

3. The power delivered to the source resistor will arrive a different times
due to the phase difference between the two waves.

4. If the reflected power returns at the same time as the delivered power
(to the source resistor), no power will flow. This because the resistor in
a Thevenin is a series resistor. Equal voltages will be applied to each side
of the resitor. The voltage difference will be zero.

5. If the reflected power returns 180 degrees out of phase with the applied
voltage (to the source resistor), the voltage across the resistor will
double with each cycle, resulting in an ever increasing current.(and power)
into the reflected wave.

This is correct for this condition. The problem with the equation comes
when cos(<90) which can easily happen.

I would suggest the equation Ptot = Ps+ Pr*(sine(A) where angle 'A' is the
angle between positive peaks of the two waves. This angle will rotate twice
as fast as the signal frequency due to the relative velocity between the
waves..

Light, especially solar energy, is a collection of waves of all magnitudes and frequencies. We should see only about 1/2 of the power that actually arrives due to superposition. The reflection from a surface should create standing waves in LOCAL space that will contain double the power of open space. I think your equation Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(A) would be correct for a collection of waves, but incorrect for the example.

I tried to read your article a couple of weeks ago, but I found myself not understanding. I have learned a lot since then thanks to you, Roy, and others. I will try to read it again soon.

So what do you think Cecil?

No, this angle is fixed by system design. If the system changes, this
angle will rotate twice as fast as the angle change of a single wave.
The equation should be OK.

Yes, I can understand that there is no change in voltage no matter what the current load is, so there can be no resistance or reactive component in the source. The ideal voltage link also said that the ideal source could maintain voltage no matter what current was applied. Presumably a negative current through the source would result in the same voltage as a positive current, which is logical if the source has zero impedance.

During the transition from negative current passing through the source to positive current passing through the source, the current at some time must be zero. How is the impedance of the perfect source defined at this zero current point? How is the impedance of the attached system defined?

The resistor in the Thevenin/Norton equivalent source is selected with some criteria in mind. What I would like to do is to design a Thevenin source to provide 1v across a 50 ohm transmission line INFINATELY long, ignoring ohmic resistance. I would like the source resistor to absorb as much power as the line, so that if power ever returns under reflected wave conditions, it can all be absorbed by the resistor. I think the size of such a resistor will be 50 ohms.

Thanks for the clarification.

Second analysis: +0.5 input reflection coefficient

I got enough email responses to my request to make me believe it might be worthwhile to put together another analysis.

The analysis I did previously is of limited use because of the total lack of any loss in the system. It has also caused conceptual difficulties because of the perfect source's -1 reflection coefficient. So I'll do another analysis with a more realistic source.

The following analysis will illustrate the startup and progress to steady state of a lossless, one wavelength, open ended 50 ohm transmission line as before. But connected to the input end of the line will be a perfect voltage source in series with a 150 ohm resistance. This is not a Thevenin equivalent circuit, because it isn't meant to be an equivalent of anything; it's simply a perfect source and a resistance, both of which are common idealized linear circuit models. The only difference between this setup and the one I analyzed earlier is the addition of the source resistance.

I'm going to make a slight change in notation and call the initial forward and reverse waves vf1 and vr1 respectively, instead of just vf and vr as before. I apologize if this causes any confusion.

When we initially connect or turn on the voltage source, the source/resistance combination sees Z0 looking into the line. So the voltage at the line input is vs(t) * Z0 / (Z0 + Rs), where vs(t) is the voltage of the perfect voltage source and Rs is the 150 ohm source resistance, until the reflection of the original forward wave returns. So I'm going to specify that

vs(t) = 4 * sin(wt)

so that the initial voltage at the line input is simply sin(wt). At any point that the forward wave has reached, then,

vf1(t, x) = sin(wt - x)

The open far end of the line has a reflection coefficient of +1, so as before the returning wave is:

vr1(t, x) = sin(wt + x)

(The change from -x to +x is due to the reversal of direction of propagation. You'll see this with every reflection.) At any time between when vf1 reflects from the output end (t = 2*pi/w) and when it reaches the input end of the line (t = 4*pi/w), the total voltage at any point the returning wave has reached is

vtot = vf1(t, x) + vr1(t, x) = sin(wt - x) + sin(wt + x) [Eq. 1]

When the returning wave vr1 reaches the input end of the line, it re-reflects to form a new forward wave vf2. But because of the added 150 ohm resistance, the source reflection coefficient is +0.5 instead of the -1 of the previous analysis, so

vf2(t, x) = .5 * sin(wt - x)

Just after the reflection, the voltage at the line input will be

vf1(t, 0) + vr1(t, 0) + vf2(t, 0) = sin(wt) + sin(wt) + .5 * sin(wt)
= 2.5 * sin(wt)

So we'll see a 2.5 peak volt sine wave at the input from the time the first returning wave reaches the source until the next one does, or from t = 4*pi/w to t = 8*pi/w. And anywhere on the line which vf2 has reached, we'll see

vtot(t, x) = 1.5 * sin(wt - x) + sin(wt + x)

When vf2 hits the far end and reflects, it creates the second reflected wave

vr2(t, x) = .5 * sin(wt + x)

So now at any point where vr2 has reached we'll have

vtot(t, x) = 1.5 * sin(wt - x) + 1.5 * sin(wt + x) [Eq. 2]

There's something worth pointing out here. Look at the similarity between Eq. 1, which was the total voltage with only one forward and one reflected wave, and Eq. 2, which is the total with two forward and two reflected waves. They're exactly the same except in amplitude -- Eq. 2 vtot is 1.5 times Eq. 1 vtot. Also notice that the equation for vf2 is exactly the same as for vf1 except a constant, and likewise vr2 and vr1. Every time a new forward wave is created by reflection from the input end of the line, a new reflected wave is created by the reflection from the far end. The reflection coefficient at the far end doesn't change, so the relationship between each forward wave and the corresponding reflected wave is the same as for any other forward wave and its reflection. So the ratio of the sum of all forward waves to the sum of all reflected waves is the same as for any single forward wave and its reflection. The relationship between forward and reverse waves determines the SWR, so this is why the source reflection coefficient doesn't play any role in determining the line SWR. No matter what it is, it creates a new pair of waves having the same ratio as every other pair.

Let's look at just one more pair of waves.

vf3 = .5 * .5 * sin(wt - x) = 0.25 * sin(wt - x)
vr3 = .5 * .5 * sin(wt + x) = 0.25 * sin(wt + x)

From the time vf3 is created until vr3 returns to the input, or from t = 8*pi/w to t = 10*pi/w, at the input end of the line we'll see

v(t, 0) = vf1(t, 0) + vr1(t, 0) + vf2(t, 0) + vr2(t, 0) + vf3(t, 0) =
3.25 * sin(wt)

For the previous round trip period the sine wave amplitude was 2.5 volts
and for this round trip period it's 3.25 volts. Where is this going to
end after an infinite number of reflections?

Well, it had better end at 4 volts, the voltage of the perfect source!
At steady state, the impedance looking into the line is infinite, so the
current from the source is zero. (A comparable analysis of the current
waves would show convergence to itot = 0 at the input.) So there's no
drop across the 150 ohm resistor and the line input voltage equals the
voltage of the source.

Let's see if we can show this convergence mathematically. The trick is
to take advantage of a simple formula for the sum of an infinite
geometric series.

If F = a + ra + r^2*a + r^3*a, . . . an infinite number of terms

then F = a / (1 - r) if |r| < 1. It's a very useful formula. I learned
it in high school algebra, but see that it's in at least one my calculus
and analytic geometry texts. Try it out, if you want, with a pocket
calculator or spreadsheet.

Going back and looking at the analysis, we had

vtot(t, x) = vf1(t, x) + vr1(t, x)

for the first set of waves. The next set was exactly 1/2 the value of
the first set, due to the +0.5 source reflection coefficient. The next
set was 1/2 that value, and so forth. So the first term of the series
(a) is sin(wt - x) + sin(wt - x) and the ratio of terms is 0.5, so

vtot(t, x)(steady state) = (sin(wt - x) + sin(wt + x)) / (1 - 0.5) =
2 * sin(wt - x) + sin(wt + x)

Using the same trig identity as in the earlier analysis,

vtot(t, x)(steady state) = 4 * sin(wt) * cos(x)

This is the correct steady state solution. You can see that it includes
the standing wave envelope cos(x), as it must.

Because superposition applies, we can add up the infinite number of
forward and reverse waves any way we want, and the total will always be
the same. So let's separately add the forward waves and reverse waves.

vf3/vf2 = vf2/vf1 = 0.5, as it is for the ratio of any two successive
forward waves
vr3/vr2 = vr2/vr1 = 0.5, as it is for the ratio of any two successive
reverse waves

So

vf(t, x)(total) = sin(wt - x) / (1 - 0.5) = 2 * sin(wt - x)

and

vr(t, x)(total) = sin(wt + x) / (1 - 0.5) = 2 * sin(wt + x)

These can be used for steady state analysis, as though there is only one forward and one reverse wave, and the result will be exactly the same as if the system was analyzed for each of the infinite number of waves individually. This is almost universally done; the run-up from the initial state is usually only of academic interest.

If we add the total forward and reverse waves to get the total voltage, the result is exactly the same as it was when we summed the pairs of waves to get the total.

Again I ran a SPICE simulation of the circuit, using a 5 wavelength line for clarity.

http://eznec.com/images/TL2_input.gif is the voltage at the line input. As predicted, it starts at 1 volt peak, remains there until the first reflected wave returns to the input end (at t = 10 sec.), then jumps to 2.5 volts. After another round trip, it goes to 3.25.
http://eznec.com/images/TL2_1_sec.gif shows the voltage one wavelength (1 second) from the source. Here you can see that the voltage is zero until the initial forward wave arrives at t = 1 sec. From then until the reflected wave arrives at t = 9 sec., it's one volt peak. From then (t = 9) until the reflected wave re-reflects from the source and returns (t = 11), we have vf1 + vr1 = sin(wt - x) + sin(wt + x). x is 2*pi radians or 360 degrees, so the voltage is simply 2 * sin(wt). And that's what the plot shows - a sine wave of 2 volts amplitude. Then vf2 gets added in at t = 11 sec, for a total of sin(wt - x) + sin(wt + x) + 0.5 * sin(wt - x), or at the observation x point, 2.5 * sin(wt). At t = 19 sec., vr2 arrives and adds another 0.5 * sin(wt) to the total, raising the amplitude to 3 volts peak. At t = 21 sec., vf3 arrives, adding another 0.25 * sin(wt) for a total amplitude of 3.25 volts. And so forth. As with the previous analysis, SPICE shows exactly what the analysis predicts.

http://eznec.com/images/TL2_5_sec.gif is the voltage at the open end of the line. For the first 5 seconds, the voltage is zero because the initial wave hasn't arrived. At t = 5 sec., the voltage at the end becomes vf1 + vr1 = 2 * sin(wt). At 15 sec., it becomes vf1 + vr1 + vf2 + vr2 = 3 * sin(wt). And so forth, just as predicted by the analysis.

Although I've used a line of the convenient length of one wavelength (or 5 wavelengths for the SPICE run), an open circuited end, and a resistive source, none of these are required. Exactly the same kind of analysis can be done with complex loads of any values at the line input and output, and with any line length. But in the general case, returning waves don't add directly in phase or out of phase with forward waves, and a wave undergoes some phase shift other than 0 or 180 degrees upon reflection. So phase angles have to be included in the descriptions of all voltages. In the general case it's much easier to revert to phasor notation, but otherwise the analytical process is identical and the results just as good.

So far I haven't seen any analysis using alternative theories, ideas of how sources work, or using power waves, which also correctly predict the voltage at all times and in steady state.

Because there's so much interest in power, I'll calculate the power and energy at the line input. But I'll put it in a separate posting.

Roy Lewallen, W7EL

Here's an analysis of the input power and energy of the system similar to the one described in my "Second analysis: +0.5 input reflection coefficient" Please refer to that posting when reading this. I'm going to make just one change to the system in that analysis: I'll use the 5 wavelength line of the SPICE analysis. This has absolutely no effect on any of the values shown in the analysis except where I gave periods of time when various equations were valid (e.g. t = 2*pi/w) -- those will be five times greater. The effect of this change is to allow use of the SPICE output as a visual aid. When speaking of the SPICE plot, I'll be referring to http://eznec.com/images/TL2_input.gif, which is the voltage at the input end of the line.

For this analysis I'm going to let f = 1 Hz, so w = 2*pi Hz.

From the voltage analysis and the SPICE plot, the initial voltage at the input of the line is sin(wt). So the voltage across the input resistor is 3 * sin(wt) (+ toward the source), and the current flowing into the line is (3 * sin(wt)) / 150 = 20 * sin(wt) mA. The average power being delivered to the line is Vin(rms) * Iin(rms) (since the voltage and current are in phase) = (0.7071 v. * 14.14 mA) = 10 mW. Since the line initially presents an impedance of Z0, this should also be Vin(rms)^2 / Z0 or Iin(rms)^2 / Z0. Let's see: Vin(rms) = 0.7071, so Vin(rms)^2 / Z0 = 0.5 / 50 = 10 mW; Iin(rms) = 0.01414 A, so Iin(rms)^2 * Z0 = 0.0002 * 50 W = 10 mW. Ok.

The input voltage remains unchanged until the first reflected wave returns at t = 10 sec (remember, we're using a 5 wavelength line and frequency of 1 Hz). So during that time we put 10 mW * 10 sec = 0.1 joule of energy into the line. Note that I could have calculated the instantaneous power for each instant, then integrated it over the first 10 seconds to get the total energy. The result would be identical.

During that first 10 seconds, the resistor is dissipating an average of Vr(rms) * Ir(rms) = 2.121 * 14.14 = 30 mW. The source is producing Vs(rms) * Is(rms) = 2.828 * 14.14 = 40 mW. So here's the story so far:

For the first 10 seconds (one round trip):
The source produces 40 mW, for a total of 400 mj (millijoules)
The resistance dissipates 30 mW, for a total of 300 mj
The line gets 10 mW, for a total of 100 mj

All the power and energy is totally accounted for, so far. The sum of power and energy delivered to the resistor and line equals the power and energy produced by the source.

As you can see from the SPICE output or the voltage analysis, the input voltage jumps to 2.5 volts at t = 10 seconds and stays there for the next 10 seconds. During that time, the voltage across the resistor is (4 - 2.5) * sin(wt), so the current drops to 1.5 sin(wt) / 150 = 10 sin(wt) mA which has an RMS value of about 7.071 mA. Using the same methods as before,

For the next 10 seconds:
The source produces 20 mW, for a total of 200 mj
The resistance dissipates 7.50 mW, for a total of 75 mj
The line gets 12.5 mW, for a total of 125 mj

We've again accounted for all the power and energy, with no need to invoke any kind of power waves.

Next the input voltage goes to 3.25 volts, so the current drops to 5 * sin(wt) mA and

For the next 10 seconds,
The source produces 10 mW, for a total of 100 mj
The resistance dissipates 1.875 mW, for a total of 18.75 mj
The line gets 8.125 mW, for a total of 81.25 mj

There's something interesting about this energy flow. Notice that the amount of power produced by the source decreases by a factor of two each cycle, and the amount of power dissipated by the resistor decreases by a factor of four each cycle. These are to be expected, since the line input voltage is increasing each time. But look at the power supplied to the line -- it actually increases during the second cycle relative to the first, then drops back. What's happening? Well, the line has an apparent impedance of Vin/Iin at any given time. Let's see what it is (the peak values have the same ratio as the RMS values, so I'll use those):

For t = 0 to 10, Vin/Iin = 1/0.020 = 50 ohms
For t = 10 to 20, Vin/Iin = 2.5/0.010 = 250 ohms
For t = 20 to 30, Vin/Iin = 3.75/0.005 = 750 ohms

The input impedance will, of course, approach an infinite value as time goes on, Vin approaches Vs, and Iin approaches zero. But during the time interval of 10 to 20 seconds, the apparent line impedance provided a better "impedance match" for the 150 ohm source than at other times, which increased the line power input during that time.

Only because we have no energy leaving the line can be calculate a total energy delivered by the source and dissipated by the resistance over an arbitrarily long time period. That is, we can find the total energy delivered if the line were connected and the source left on forever. We can use the same formula for summing an infinite series as used in the voltage analysis to find that:

The source produces a total of 400 / (1 - 0.5) = 800 mj
The resistor dissipates a total of 300 / (1 - 0.25) = 400 mj

from which we see that a total of 400 mj has been supplied to the line. If we were to quickly replace the source and resistor with a 50 ohm resistor across the line and no source, what should happen? Well, we have forward and reverse waves of 2 volts peak traveling on the line, so the end voltage should immediately drop to 2 * sin(wt) as the reverse traveling wave exits with no further reflections from the input end of the line, and the forward wave moves toward the far end. So the 50 ohm resistor would have an RMS voltage of 1.414 volts across it, and a dissipation of (1.414)^2 / 50 = 40 mW. This constant dissipation should continue until the line is completely discharged, which will take one round trip time or 10 sec. The total energy removed from the line and dissipated during this time is 40 mW * 10 sec = 400 mj, which is exactly the amount we put into the line during the charging process. All the energy produced by the source is accounted for. I think I can set this maneuver up with SPICE, and I'll do so if anyone who might be skeptical would be convinced by the SPICE output.

A caution is in order. This analysis was greatly simplified by the lack of any energy storing devices other than the transmission line. That is, there was no reactance at either end of the line. An equally accurate analysis could be done with reactances present, but calculation of energy from power would have to account for the temporary energy storage in the reactive components. Also, if a resistance-containing load is connected to the output, it will also dissipate power and energy, so that would also have to be accounted for. The bottom line is that care should be taken in applying this method to more complex circuits without suitable modification.

I've completely accounted for the power and energy leaving the voltage source, being dissipated in the resistor, and entering the line, at all times from startup to steady state, and done it quantitatively with numerical results. And I did this without any mention of propagating waves of power or energy. It was done very simply using Ohm's law and elementary power relationships, with the only variable being the line input voltage calculated from the voltage wave analysis. I offer a challenge to those who embrace the notion of traveling waves of average power or other alternative theories to do the same using mathematics and premises consistent with the alternative theory. Until such an analysis is produced, I remain unconvinced that any such theory is valid. *Any* analysis has to produce results consistent with the law of the conservation of energy, as this one has.

Makes a huge difference in the analysis.

>the impedance
>of the generator is irrelevant.

The impedance perhaps, but not the voltage. I specifically offered a
difference of sources (Norton vs. Thevenin). The impedance is the
same either way, the voltage is not. As you introduce power later in
this response, power at the source is even more contentious. As such,
we can drop this altogether.

>Ah. The challenge of written precisely. Consider the

Still doesn't make sense, and I wouldn't attribute it to precision
seeing that you've written the same thing twice.

>Again, the poor writing meant a bit further to left
>from the end.

Yes, if you are in a left-right progression, further is more to the
right. There is the ambiguity of "end effect."

>> Want to explain how you double the stored voltage in the distributed
>> capacitance of the line without current? ï¿½
>
>The energy formerly present in the inductance of the line
>has been transferred to the capacitance.

That is always so. You haven't offered anything differentiable from
always, where previously (and later in your response, here) you
suggested current stopped flowing even when voltage was doubling.

>> The definition of capacitance is explicitly found in the number of

You don't explain where the extra voltage is. There is a double
voltage to be sure, but you have not exactly drawn a cause-and-effect
relationship.

>Challenges with the referent.
>The former view is that a voltage of 2*V is propagating

Sounds more like a problem for the challenged (i.e. there is no
difference between 2*V and V+V).

Does it matter? It is another step. That should be obvious for the
sake of superposition.

>"The tread continues to flow to the end of the line
>and be reflected as the leading edge travels back to
>the source."

>
>I am not sure that that is any clearer.

Not particularly, since we now have three things moving:
1. Step;
2. Tread;
3. Leading Edge.
It would seem to me that both 1 and 2 have a 3; so what are you trying
to say with the novel introduction of two more terms?

>> >And this is the major weakness in the model.
>>
>> Which model? ï¿½
>
>The "no interaction" model.

And which model is the "no interaction" model? The former, or the
latter?

>> >the line that has a voltage of 2*V and *zero* current.
>>
>> Does a step function flow? ï¿½
>
>Perhaps the "tread"? But then should the step change
>be called the "riser"?

So now we have four things moving:
1. Step;
2. Tread;
3. Leading Edge.
4. Riser
It would seem to me that both 1,2 and 4 have a 3; so what are you
trying to say with the novel introduction of three more terms?

>> As for "zero" current, that never made
>> sense in context here.
>
>Somewhat clarified, I hope. But for clarity, the
>current to the right of the leftward propagating
>step is zero.

So now the leftward propagating step is
1. Step;
2. Tread;
3. Leading Edge;
4. Riser?

If I simply discard the last three invented terms; went out on the
thin limb of interpretation; then, in my mind's eye I would see that,
yes, no current is flowing to the physical right of the transient (the
only thing that is moving - as evidenced through voltage).

>> >A trivial example is connecting to 10 volt batteries

Makes quite a difference. Perhaps not in the math, but certainly in
the concept.

>> However, by this forced march through the math, it appears there are
>> two batteries in parallel; (series) bucking; with a parallel resistor.
>
>So in the end, successful communication of the schematic.

Actually no. You describe a resistor in a series loop; I describe a
resistor in parallel. Consider the repetition of your last statement
above:
>positives connected using the resistor.
Positives connected through the resistor (the sense of "using" the
resistor as connector)?
Or positives connected, then using the resistor (where it is also
connected, but unstated as such) to the negatives?

>> It would seem if you knew the charge, you already know the energy; but
>> the power?
>
>Just energy per unit time. We know the energy distribution
>on the line, so we know the power at any point and time.

Time has not been quantified, whereas voltage, hence charge, hence
energy has. Why introduce a new topic without enumerating it, when
its inclusion adds nothing anyway? You don't develop anything that
explains the step in terms of power. You don't use power anywhere. In
fact we then step into the philosophy of does a line actually move
power, or energy? That debate would cloud any issue of a step's
migration, reflection, or any of a spectrum of characteristics that
power has no sway over.

>> >But when
>> >two waves are simultaneously present, it is only
>> >legal to superpose the voltage and the current.
>>
>> And illegal if only one is present? ï¿½
>
>No. Legal to also compute the power.

Please note you start your sentence with a "But." Sentences (much
less paragraphs) are not started with coordinating conjunctions. When
you use "but," the logical implication is that you are coordinating:
two-waves with an equal ranking and unexpressed: one-wave.

One may also use "but" at the beginning of a sentence as a logical
connector between equal ideas (a transitional adverb); however, you
don't have anything in the preceding, original paragraph other than a
single wave.

I do not see anything distinctive about two waves over one wave until
your recent injection of power (not at all in the original), and to no
effect except to raise the objection (rather circular and unnecessary
inclusions to abandon the discussion of reflection in rhetorical
limbo). Apparently your transition spans many postings to a festering
point by Cecil (this is, of course, another one of my
interpretations).

>> >Earlier you asked for an experiment. How about this

You seem to be in self-contradiction when you describe voltage doubles
without current flow.

>> If, for some infinitesimal line section, there is no current through
>> it, then there is no potential difference across it.
>
>Or did you mean along it?

A point well made in the scheme of precise language. Yet and all,
taken singly (one/either conductor) or doubly (a transmission line
section); then the identical statement remains true with both

interpretations for the step condition.

Of course, a lot may be riding on whether you are speaking of a step
function, or a pulse. Seeing the original was explicit to step, and
never introduces pulse; then there is no current flow as I responded:
>> Hence, the when is some infinitesimal time before the waves of equal

>
>That they bounce rather than pass silently.

How do you introduce recoil or maintain momentum without energy? Odd.

Please remove my need to perform interpretation and give me a more
succinct accounting. Further, limit this to one scenario (this last
failed example is certainly dead in the water as far as collisions
go).

Hi Roger,

One confusion would seem to originate in your reliance in resistors.

A resistor (R) is NOT the series (or for Norton the parallel) passive device - it is an Impedance (Z).

This misapplication (R) was perpetuated by Edison when he battled Westinghouse for funding of power generation projects. He would invariably craft the resistor (R) into the equation for the bankers to prove DC was more efficient that AC systems, when in fact the engineering (Z) proves quite the contrary.

I suppose the bankers bought it (R) at the outset, but market economics (Z) hammered Edison into the ground when the bookkeeping of AC made their investors rich at the expense of DC.

This also raises issues of the confusion over conjugate matching and Z0 matching where many correspondents here freely intermix the two's characteristics as though they belong to one or the other (or both, or neither).

It's also reasonable to talk about positive or negative reflection coefficients when you're restricting the possibilities to ones having an angle of zero or 180 degrees. This would be the case, for example, when dealing with lossless lines (purely real Z0) connected to other lossless lines or to a purely resistive source or load.

-= why. the security services? -=
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=
```

You may ask,. why do I think the "they" referred to are the security services? Is there any evidence that there is. a single source, as opposed to a loosely based "whispering. campaign" amongst many people? Even if there is a single source, is there any evidence that "they". are professional "buggers" as opposed. to amateurs, or perhaps people working for a privately funded. organization?

a) As to the question of a single source. versus something more fragmented; it is quite obvious that there is a single source. from the way the campaign has been carried. out. Since things have been repeated verbatim which were said in my home, there. must be one group which does the watching and listening. Since. on several occasions (mainly during travel) people have been planted. in close proximity and rehearsed in what they were to say, it follows that someone. must have done the planning for that, and again a single source is. indicated.

b) So why couldn't it be amateurs? Why couldn't. it be a private organisation, for example a private detective agency paid. to manage the campaign and undertake the. technical aspects? Some detective agencies are unscrupulous as has been proved on the occasions. in the past when they've been exposed or caught; they. too can have access to the bugging technology deployed; and there are reported cases. of MI5 paying private eyes to do their dirty work (against peace campaigners and. similar enemies of the state) on the understanding that if they were caught then they could. deny all knowledge. Why. couldn't that be the case?

The main. factor pointing to direct security service involvement (as opposed to amateurs or MI5 proxies). is the breadth of their access to the media in particular, and the fact that the television companies are. so involved in the campaign. The. BBC would not directly invade someone's home themselves, since it would not be within. their remit to allocate personnel or financial resources to do so. An organisation of their stature would not. take part in a campaign set up by private sources. The. only people they would take material. from would be the security services, presumably on the assumption that if. the cat ever flew out of the bag yowling it would be MI5 who would take. the consequences.

State. sponsorship for these acts of psychological terrorism is also indicated by duration; support for over. six years for a team of three or four people would be beyond the. means and will of most private sources.

The viciousness of the slanders and personal denigration also. points to MI5; they traditionally "protect". the British state from politicians of the wrong hue by character assassination, and in this case. are using their tried and. tested methods to murder with words an enemy they have invented for. themselves.

And there are precedents.. Diana and Hewitt were alleged to have been filmed "at it" by an Army intelligence team which had. operated in Northern Ireland, these allegations were made by someone called Jones. who had been on. the team. His statements were denied by the defence establishment who tried to character-assassinate by. describing him as the "Jones twins". Funny how if. you tell the truth, then you must be ill, isn't it? Thought only communists. behaved like that?

Hewitt later said that he'd been. spoken to by someone in the army who revealed the existence of videotapes of him and. Diana, and that the tapes would be published if any. attempt was made by them to resume their association.

-=-=-=-=-=-=-=-=-=-=-=-=
-= harassment at. work -=
-=-=-=-=-=-=-=-=-=-=-=-=

Once I stopped watching television and listening to the. radio at the end of 1990, "they" had to find other ways of. committing abuses. So they took what must. be for them a tried and tested route; they get at you by subversion of those around you. Since they wouldn't be able to do that with my. family or friends, that meant getting at people in the workplace to be. their mouthpieces. and do their dirty work for them.

They supplied my employers in Oxford with details from what was. going on in my. private life, and what I and other people had said at my home and accommodation in Oxford. So people at. work repeated verbatim words which had been said. in my home, and repeated what I'd been doing recently. Often the most trivial things, the ones from your domestic life,. are the ones which hurt most. One manager in particular at Oxford continuously. abused me for ten months with verbal sexual abuse, swearing, and. threats to terminate my. employment. After ten months I was forced to seek psychiatric help and start taking medication, and was away from work for two. months. I spoke later with a solicitor about what had happened at that company;. he advised it. was only possible to take action if you had left the company as a result of harassment, and such an action would have to. be started very soon after leaving.

Over a year later. the same manager picked on another new worker, with even more serious results;. that employee tried to commit suicide with an overdose as a result of the ill-treatment, and was forced to leave. his job. But he didn't take action against the company, either.. Abuse at work is comparable to that elsewhere in that. tangible evidence is difficult to produce, and the. abusers will always have their denials ready when challenged. And even if a court accepts what you say happened, it. still remains to prove. that abuse causes the type of breakdown I had at the end of 1992. In a recent case before a British court,. a former member of the Army brought a case against others who had. maltreated him ten years previously. Although the court accepted. that abuse had occurred, it did not agree that depressive illness necessarily followed,. and denied justice to the. plaintiff.

This is true.

> During the transition from negative current passing through the source
> to positive current passing through the source, the current at some time
> must be zero.

This would occur, for example, when the output terminals
are open circuited. Or connected to something that had
the same open-circuit voltage as your source.

> How is the impedance of the perfect source defined at
> this zero current point?

This is not a different question than: How is the
resistance of a resistor defined when it has no
current flowing in it?

It continues to satisfy the relation V = I * R,
though one can not compute R from the measured
V and I.

> How is the impedance of the attached system
> defined?

It is unknown, but has a voltage equal to the
voltage of the source.

> The resistor in the Thevenin/Norton equivalent source is selected with

> think the size of such a resistor will be 50 ohms.

That is the correct value to not have any reflections
at the source.

But do not expect the power dissipated in the resistor
to increase by the same amount as the "reflected power".
In general, it will not. This is what calls into question
whether the reflected wave actually contains energy.

Do some simple examples with step functions. The math
is simpler than with sinusoids and the results do not
depend on the phase of the returning wave, but simply
on when the reflected step arrives bach at the source.

Examine the system with the following terminations on
the line: open, shorted, impedance greater than Z0,
and impedance less than Z0.

Because excitation with a step function settles to
the DC values, the final steady state condition is
easy to compute. Just ignore the transmission line
and assume the termination is connected directly
to the Thevenin generator. When the line is present,
it takes longer to settle, but the final state will
be the same with the line having a constant voltage
equal to the voltage output of the generator which
will be the same as the voltage applied to the load.

Then do the same again, but use a Norton source. You
will find that conditions which increase the dissipation
in the resistor of the Thevenin equivalent circuit
reduce the dissipation in the resistor of the Norton
equivalent circuit and vice versa.

This again calls into question the concept of power
in a reflected wave, since there is no accounting
for where that "power" goes.

Given your previous writings, I suspect that you have
a solid understanding of the behaviour of an open-circuited
transmission line excited with a step function.

Perhaps you could make an attempt at writing a clear
description of the behaviour of such a system in terms
of charge flow and storage. Since "wave" is a word
overloaded with meanings, it would be good not to use
it in the description.

Once a clear description exists, I can extend it
using the same clear terminology to illustrate

the points of interest.

False. There can be a large difference in the output
impedance of an amplifier designed to drive a 50 ohm
load and a 50 ohm Thevenin equivalent circuit.

> source is turned off for purposes of superposition.

I am not sure you have the methodology quite correct.
The source is not turned off; its output is set to 0.

It does what every ideal voltage source will do when
set to a voltage; maintain that voltage. Through all
of this, the impedance of the ideal source remains 0.

Now it turns out that an ideal voltage source set
to zero volts can be replaced by a short which also
has an impedance of 0 and produces no volts. But this
does not alter that the ideal source always has an
impedance of 0.

Analogously, an ideal current source always has an
infinite impedance. When set to 0 amps, it behaves
exactly like an open circuit.

You should really stop repeating this to yourself. No
one is attempting to violate the principle of conservation

of energy.

By continually repeating this mantra, you convince yourself that you do not need to examine the claims of those who disagree with you. So you do not examine and understand their claims. This seriously limits your capability to learn.

If you truly wish to demolish the claims, you should study them in great detail, then write an even better and more persuasive description of the claim than did the original author. Then identify and point out the flaws.

As it stands, you do not examine the claims, but immediately coat them with the tar of "violates conservation of energy" or some other mantra and walk away.

It does not lead to learning.

Gene Fuller wrote:
> For future reference, however, just remember: Fields first, then power
> or energy. That's the way superposition really works.

Way back before optical physicists could measure light
wave fields, they were dealing with reflectance,
transmittance, and irradiance - all involving power
or energy. They are still using those concepts today
proven valid over the past centuries. Optical physicists
calculate the fields *AFTER* measuring the power density
and they get correct consistent answers.

Use whatever method works for you but don't try to change
or replace the body of the laws of physics that was in place
before your grandfather was born. Your rejection of those
laws of physics from the past centuries is why you are so
confused today by your steady-state short cuts. It's why
Keith doesn't recognize a 1.0 reflection coefficient when
it is staring him in the face. It's why Roy rejects energy
in reflected waves. Optical physicists have known for
centuries where the energy goes. That RF engineers are
incapable of performing an energy analysis is sad.

Irradiance (intensity) is a power density. Many problems
in physics can be solved without even knowing or caring
about the strength of the fields. Here is one such lossless
line problem for you.

100w--50 ohm line--+--1/2WL 300 ohm line--50 ohm load
Pfor1-->|-->Pfor2
Pref1<--|<--Pref2

Without using fields, voltages, or currents: Calculate
the magnitudes of the four P terms above. Using the RF
power reflection-transmission coefficients, please explain
the magnitude of Pref1. If you cannot do that, you really
need to broaden your horizons and alleviate your ignorance.

Quoting HP AN 95-1: "The previous four equations show that
s-parameters are simply related to power gain and mismatch
loss, quantities which are often of more interest than the
corresponding voltage functions."

> Would you please quote a reference that addresses
> the subject of reflection coefficients from Thevenin
> or Norton equivalent sources?

Seshardi, "Fundamentals of transmission lines and
electoromagnetic fields", page 19-21, explains
reflection diagrams and the generator is styled
after Thevenin. Page 21 says

RHOg = (Rg-R0)/(Rg+R0)

RHOg is the reflection coefficient at the generator
and Rg is the value of the output resistor. The
exposition has not yet generalized to Z so is still
in terms of R.

But do not feel limited to Seshardi. Any decent
book on transmission lines will cover the subject.

Or even easier, google '"lattice diagram" reflection',
"reflection diagram" or "bounce diagram". You will
find many examples using Thevenin sources.

But this same information has been repeatedly provided
and ignored. Will this time be different?

However, after the interference patterns have been
established, the reflected waves do not encounter that
source impedance. That is why the reflection coefficient
seen by the reflected waves is relatively unrelated to
the value of resistance in a Thevenin equivalent circuit.

You need to complete step 3 of the superposition process
to realize exactly what is happening. Reference the
irradiance equation from the field of EM wave optics
to ascertain the interference levels. What do you have
to lose by alleviating your ignorance?

Keith, until you take time to understand destructive and
constructive interference, you will never understand what
is happening inside a source and will be forever confused
by your blinders-on-come-hell-or-high-water method of
thinking. Optical physicists figured out a couple of
centuries ago exactly what you are wrestling with now.
Your present problem was already solved before your
grandfather was born.

Please reference a good book on optical EM waves
for a complete answer. It is *not me* making it work.
It is a body of physics knowledge that has existed
since long before you were born. It should have
been covered in your Physics 201 class. That you
are apparently unaware of such is a display of
basic ignorance of the science of EM waves.

The basic theory applies specifically to coherent
waves (which are the only EM waves capable of truly
interfering). CW RF waves are close enough to ideal
coherency that the theory works well. It would no
doubt work for a coherent Fourier series as well
but I don't want to spend the time necessary
to prove that assertion.

> How do you compute
> Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(A)
> for a pulse or a step?

The above equation applies to coherent signals.
It is known not to work when the signals are not
coherent because the angle 'A' never reaches
a fixed steady-state value.

> Or is your approach limited to sinusoids?

Again, it is not *my* approach and is described in any
textbook on "Optics" including Hecht and Born & Wolf.

I don't think it is organised,just a couple of wierdos. You have the
one
guy who lives in South London and then the other wierdo who lives way
up
North of Chicago. Actually they are so wierd that they don't even
communicate
with each other. Neither of the them work because of mental disability
which is not a bad thing as when they are caught they can be put in a
looney bin for a long while. Eventually somebody who lives nearby
will pay them a little visit and present them with a parcel or
something.
Fortunately their posts are easily recognisable so one can move on.
If the fphantom wave thing goes on much longer I may have to
communicate
with both of these wierdoos for a change in pace!

I assume that you have not provided a reference to support
this assertion because you have not been able to find one.

Unfortunately optics do not do well at explaining
transmission lines since they do not extend down
to DC.

I have yet to find anything about transmission lines
that needs constructive and destructive interference
for explanation. Volts, amps and superposition seem
to be able to do it all, and have the added benefit
of explaining the behaviour for step functions and
pulses. With the volts, amps and superposition,
sinusoids are just a special case of the general
one.

I am unsure why some are content to constrain
themselves to solution techniques and explanations
that only work on the special case of sinusoids.

I accept your "NO" and agree that EM waves are
incapable of providing solutions for pulse or
step excitation.

But why don't you just say so clearly.

> Please reference a good book on optical EM waves
> for a complete answer.

Given that optical EM waves are only capable of
solving a subset of the uses of transmission lines,
it is not obvious why I should study them when
I can invest in learning approaches that will do
the whole job.

> It is *not me* making it work.

True. And as you have said, it does not work
for pulses or steps.

Some who claim to have studied them thoroughly
seem to be constrained by their limitations. Is
that better?

Well, others more knowledgeable than I in optics
have disputed whether *your* approach accurately
represents those described in the textbooks.

In any case, being applicable only to sinusoids
limits the general applicability to transmission
lines which happily work at DC.

Anyone who will take the time to understand and is capable
of understanding, will understand. What I am reporting are
centuries-old proven scientific concepts. Readers need only
reference an optics textbook for irradiance, reflectance,
and transmittance. "Optics", by Hecht is easy reading.

> Is this a Thevenin source? If so, what is the internal resistor set to in
> terms of Z0?

The example was a Thevenin source driving a 1/2WL open
line through a source resistor equal to Z0, e.g. 50 ohms.

> For condition number 2 below, is this a Thevenin equivalent resistance?

Yes, all the rules of superposition and Thevenin equivalency
are being followed.

> 1. To add the total power of each wave and then also add the power
> reduction of the phase relationship, would be creating power unless the
> cos(A) is negative. Something seems wrong here, probably my understanding.

Yep, I haven't given the other corresponding equation. The
pair of equations that satisfy the conservation of energy
requirements are (in Ramo&Whinnery Poynting vector notation):

|Pz+| = P1 + P2 + 2*SQRT(P1*P2)cos(A) eq.1

|Pz-| = P3 + P4 + 2*SQRT(P3*P4)cos(-A) eq.2

In a transmission line, the Poynting vector for Pz+ and the
Poynting vector for Pz- are pointed in opposite directions.

The destructive interference, as you observed, carries a
negative sign. This negative sign does NOT create energy.
It means that some excess amount of destructive interference
energy must go somewhere. It naturally goes into constructive
interference somewhere else. Please see:

http://www.mellesgriot.com/products/optics/oc_2_1.htm

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

> 2. The two voltages should be equal, therfore the power delivered by each
> to the source resister would be equal.

Under each of the two superposition steps, yes. However, when
the signals are combined, interference results, and the power
in the source resistor is reduced to zero. That "excess" energy
must go somewhere and it appears as constructive interference
redistributed toward the load. See the web pages above.

> 3. The power delivered to the source resistor will arrive a different times
> due to the phase difference between the two waves.

We are talking average power. Please don't get bogged down in
instantaneous power which would be the same when integrated.

> 4. If the reflected power returns at the same time as the delivered power
> (to the source resistor), no power will flow. This because the resistor in
> a Thevenin is a series resistor. Equal voltages will be applied to each side

Yes, the result is destructive interference.

> 5. If the reflected power returns 180 degrees out of phase with the applied
> voltage (to the source resistor), the voltage across the resistor will
> double with each cycle, resulting in an ever increasing current.(and power)

Good time to switch over to a Norton equivalent.

> This is correct for this condition. The problem with the equation comes
> when cos(<90) which can easily happen.

That's no problem at all. It is just constructive interference
which implies destructive interference somewhere else. Destructive
interference must always equal constructive interference to avoid
violation of the conservation of energy principle.

> Light, especially solar energy, is a collection of waves of all magnitudes

> correct for a collection of waves, but incorrect for the example.

A collection of waves is not likely to be coherent so the equation
would not work. That equation works for any coherent EM wave. CW RF
waves are coherent.

> I tried to read your article a couple of weeks ago, but I found myself not
> understanding. I have learned a lot since then thanks to you, Roy, and

You might want to pick up a copy of "Optics", by Hecht
available from http://www.abebooks.com Please pay close
attention to the chapters on interference and superposition.

> So what do you think Cecil?

Also try HP's AN 95-1, an s-parameter app-note available on the
web. Pay close attention to what they say about power and what
happens when you square the s-parameter equations. Surprise!
You get the power interference equation above.

> size of such a resistor will be 50 ohms.

If you allow reflected energy to flow through the
source resistor, destructive interference is often
the result and the resistor therefore will not
dissipate the reflected power.

The only way to get the source resistor to dissipate
all of the reflected power is to cause total constructive
interference within the source. That requires all of the
energy from the load side of the system.

When the source rejects reflected energy due to destructive
interference, that energy has no choice except to reverse
direction and flow back toward the load as constructive
interference energy.

Maybe you should reconsider the circulator+load-resistor?

The equation can NOT be OK for anything except a single interaction
point. It can not be used to plot the interaction between waves because
the wave location information is not present.

In the last 24 hours, Roy posted a revised analysis that contains
results useful here. He presented a voltage example that resulted in a

steady state with steady state voltages 4 time initial value. Under superposition, this would equate to 4 times the initial power residing on the transmission line under the conditions presented. This concurs with other authors who predict power on the transmission line may exceed the delivered power due to reflected waves.

Your equation "Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(A)" is taken from illumination and radiation theory to describe power existing at a point in space near a reflecting surface. If we consider space to be a transmission media, and the reflecting surface to be a discontinuity in the transmission media, then we have a situation very similar to an electrical transmission line near a line discontinuity.

It is entirely reasonable to consider that the reflection ratio between the space transmission media and the reflective surface would result in an storage factor equaling 4 times the peak power of the initial forward wave. By storage factor, I simply mean the ratio of forward power to total power on the transmission media under standing wave conditions.

Under open circuit conditions, a half wavelength transmission line will have a storage factor of 2. Roy presented an example where the storage factor was 4. Perhaps the space transmission media also has a storage factor of 4 under some conditions, as described by "Ptot = Ps + Pr + 2*SQRT(Ps*Pr)cos(A)".

Very interesting! It makes sense to me. I must be gone most of the day today so will be QRT for a while.

I am gaining an appreciation for the time boundaries here. To properly account for the power, we would need to integrate the source power over the entire time from switch on to switch off plus the time required for the reflected wave to completely return and die out.

If we consider the extended time period, within that period the power delivered by the source should equal the power dissipated by the resistor. The forward and reflected waves should only serve to be storage for the power during portions of the extended time period.

Hi Dave,

That is pretty obscure, which means you know more than I do.

On the other hand, the long-line to DC for me a few days ago was
American Airlines SEA to BWI; then back from National; both through
DFW.

This is hardly different from the other example. Total destructive
interference is still occurring in the source resistor resulting
in total constructive interference toward the load. The forward
and reflected powers are equal to 0.04 watts. All of the voltages
and currents are easy to calculate after that. What else do you
need to know?

Hi Keith,

I do, but I haven't dwelled on the matter too much since my days in RADAR where a Pulse Forming Network could provide a kick from a very big bottled Thyratron. I can also in those early days recall an inadvertent opening of a circuit to a constant current device - another kick.

As for naming the multitude of combined stepped wave shapes, front porch and back porch regularly make their appearances a Trillion times an hour.

I simply couldn't wade through the myriad issues that you were trying to pull together. I prefer to drill down on one thing at a time and then bring them together. For instance, your last example of dueling sources was clearly blighted and allowed for easy dismissal. However, its inclusion was distinctly at odds with the other discussion which reveals the hazard of the shotgun style of answering all of Cecil's objections in one breath.

Cecil's crafted problems immediately fail with one detail, there is no reason to pursue them all. One need only review the "purpose" of this thread being

Clearly, Cecil was the most dazed and confused guru when I drilled down on this "purpose" of his own choice, on his own terms. The subsequent 450 postings have merely roiled in the seascape on sloshing waves when this anchor of "purpose" was cast off.

>Perhaps you could make an attempt at writing a clear
>description of the behaviour of such a system in terms
>of charge flow and storage. Since "wave" is a word
>overloaded with meanings, it would be good not to use
>it in the description.

I can appreciate your attempt to confine it to charge flow, but for me that leading edge merely introduces a wide spectrum of RF rather than restricting the topic. If I were to give any thought to the minutia of current flow along infinitesimal sections, it has long since been focused in the realm of coulomb blockades at the nano scale of quantum dots, and where sound waves comfortably migrate in the 100s of THz. I think few (make that zero) here are terribly interested in that side-bar.

>Once a clear description exists, I can extend it
>using the same clear terminology to illustrate
>the points of interest.

Methinks you are going to suffer it being ignored by the target of your intentions (Cecil?). His affliction of Netzheimers only allows any topic to be discussed to its logical confusion.

If, for the sake of lurkers, any topic merits an indepth study, it is best left to publishing at a page. I committed several hundred pages to fractals in the past, and Chip never manage to summon up more than half a dozen; and certainly never any coherent theory. Drilling down on the supporter's stated interest, on his own terms, almost always rents open the seams of failure. Again, the points of interest I elaborated on were consumed by the very few (maybe two, and mostly to their astonishment of so much effort going to so much "so what?"). We can all agree that the march of time has ravaged any millennium aspirations of the dawn of the fractal age.

Yes, you did deliberately avoid mentioning the energy in
the forward and reflected waves in the stub. So what? The
energy supplied to the stub is in the form of EM wave
energy. As long as it is not transformed into a different
type of energy, it will remain EM energy whether you choose
to ignore it or not. Your failure to mention ExH energy/sec
doesn't mean it ceases to exist. The EM wave energy is still
there moving at the speed of light in the medium. It is exactly
equal to the energy necessary to support the forward and
reflected power.

Roy, if you think that your failure to mention reality changes
reality, I feel really sorry for you but it is not unusual for
gurus to suffer from delusions of grandeur.

Perhaps you misunderstood the purpose of the question. Traveling waves are basically uniform in amplitude along the length of a transmission line. Why would any heating associated with a traveling wave anything other than uniformly distributed?

Virtually every EM wave you see with your own eyes is
a reflection. For you to argue that there is no energy
in those reflected EM waves is ridiculous in the extreme.
Exactly how do your optic nerves detect photons that
contain no energy? Hey, maybe that's why you are
hallucinating. :-)

> This again calls into question the concept of power
> in a reflected wave, since there is no accounting
> for where that "power" goes.

That you fail to understand where the EM reflected wave
energy goes is simply ignorance. Please alleviate your
ignorance on the subject and the problem will go away.
Optical physicists have been tracking that energy for
centuries. Where have you been for the past three
centuries? :-)

I suggest you start with Eugene Hecht's chapter on
interference in "Optics". You will learn about
destructive interference, constructive interference,
and why those two must balance. All of the ExH energy
in an EM wave is conserved. You are simply ignorant
of how that energy is conserved.

I'm not the one who is ignoring that information.
Where are your calculations involving destructive
and constructive interference? Until you provide
that information, you are just blowing smoke.

When are you going to realize that the effective
reflection coefficient for a source supplying zero
power is |1.0|?

You can certainly use the reflection coefficient
that you posted but that is only a small part of
the total reflection story.

> 2*SQRT(Ps*Pr)cos(A)".

Power is neither stored nor conserved, so a power "storage factor" is meaningless. Consider a very simple example. Let's charge a capacitor with a constant current DC source. We'll apply 1 amp to a 1 farad capacitor for 1 second. During that time, the power begins at zero, since the capacitor voltage is zero, then it rises linearly to one watt as the capacitor voltage rises to one volt at the end of the one second period. So the average power over that period was 1/2 watt, and we put 1/2 joule of energy into the capacitor. (To confirm, the energy in a capacitor is 1/2 * C * V^2 = 1/2 joule.) Was power "put into" or stored in the capacitor?

Now we'll connect a 0.1 amp constant current load to the capacitor, in a direction that discharges it. We can use an ideal current source for this. The power measured at the capacitor or source terminals begins at 0.1 watt and drops linearly to zero as the capacitor discharges. The average is 0.05 watt. Why are we getting less power out than we put in?

"Where did the power go?" is heard over and over, and let me assure you, anyone taking care with his mathematics and logic is going to spend a long time looking for it. So in this capacitor problem, where did the power go?

It takes 10 seconds to discharge the capacitor, during which the load receives the 1/2 joule of energy stored in the capacitor. Energy was stored. Energy was conserved. Power was neither stored nor conserved.

Roy Lewallen, W7EL

I provided the reference a number of times and you
chose to ignore it. The reference is the chapter on
interference in "Optics", by Hecht.

> Unfortunately optics do not do well at explaining
> transmission lines since they do not extend down
> to DC.

On the contrary, most physics books on "Light" do
indeed extend down to DC. I'm surprised you don't
know that. "Light" and "visible light" are two
entirely different subjects. "Light" covers all
EM waves all the way down to DC.

> I have yet to find anything about transmission lines
> that needs constructive and destructive interference

Source record: 30199

People who are having trouble with the concept of a -1 voltage reflection coefficient for a perfect voltage source might benefit from the following exercise:

Look at my first analysis, where the perfect source was connected directly to the transmission line. Make no assumptions about the impedance or reflection coefficient it presents. Then, when the reflection of the initial forward wave returns, calculate the value the re-reflected wave must have in order to make the sum of the waves present, which is the line input voltage, equal to the perfect source voltage. The voltage of the perfect source can't change, by definition. The ratio of the re-reflected wave to the returning wave is the voltage reflection coefficient (since we're dealing with voltage waves).

I'll do it for you:

The forward wave was vf(t, x) = sin(wt - x)
The returning wave was vr(t, x) = sin(wt + x)

The returning wave will strike the input end of the line and create a new forward wave with value vf2(t, 0) = Gs * vr(t, 0) at the input, where Gs is the source voltage reflection coefficient.

Before the first forward wave returns, we have only vf(t, 0) = sin(wt) at the input end of the line. This is of course the source voltage.

After the wave arrives and re-reflects, we have at the input end

vtot(t, 0) = vf(t, 0) + vr(t, 0) + vf2(t, 0)
= vf(t, 0) + vr(t, 0) * (1 + Gs)

This must equal the source voltage, which is the line input voltage, and cannot change. So plugging in values:

sin(wt) = sin(wt) + sin(wt) * (1 + Gs)

Solving for Gs => Gs = -1

I have made no statement about the "impedance" of the perfect source. The only thing I've required is that the voltage remains constant, which is the very definition of a perfect source. You can do a similar exercise to show that the voltage reflection coefficient of a perfect current source is +1.

It's the consequence of having *two* traveling waves, which occurs any time the line isn't terminated with its characteristic impedance. Betcha yours wasn't.

That's not a given and is in fact a falsehood.
RF waves are a subset of light waves. Perhaps
you are erroneously confusing "light waves" with
"visible light waves".

When a light wave is red-shifted to 10^12 times
its original wavelength, does it cease to be a
light wave? Feel free to answer yes or no.

> Well, others more knowledgeable than I in optics

A rate of 10 joules/sec is valid at any time in which there is a 10 volt differential and a current flowing at a rate of one coulomb per second (and a half coulomb in a half second, and a thousandth of coulomb in a millisecond, and like that).

> Exactly how long is that instantaneous

> 2*SQRT(Ps*Pr)cos(A)".

Visualize visible interference rings between two equal
waves each of P magnitude, where the darkest of the rings
is completely black. If it is not obvious, the power in
the brightest of the rings would have to be 4P for the
energy to average out to the 2P in the source waves. That's
all there is to "black" destructive interference vs "bright"
constructive interference. (4P+0P)/2 = 2P = average power
It's a no-brainer for most folks.

On the source side of a Z0-match, the reflections are "black".
On the load side of a Z0-match with reflections, the forward
wave is "bright". What could be simpler?

Depends upon which valid model one is using.

1. Reflection Model - the energy is stored in the
forward and reflected traveling waves.

2. The LCLCLC transmission line model - the energy
is alternately stored in the L's and C's.

3. The Sloshing Model - I'll let Roy handle that one.

It was the simple scalar addition of two traveling waves
that caused it to happen. Since standing waves contain no
real power, they cannot directly supply any real power.

Only traveling waves, with their voltages and currents
in phase, can supply real power. Each traveling wave
delivers some of its energy which is converted into heat.

If you believe that steady-state standing waves can supply
real power, please explain how real power can be obtained
when the voltage and current are 90 degrees out of phase.

"Way back" is irrelevant. One only needs to open a serious text book on Optics, such as Born and Wolf, to see how optical physicists perform analysis today.

>
> Quoting HP AN 95-1: "The previous four equations show that

I agree with this statement completely (surprised??). S-parameter analysis is very useful. However, the "corresponding voltage functions" are equally valid, even if not as "interesting". What you might also notice in AN 95-1 is that there is no mention of incident and reflected waves on a transmission line, each carrying energy (or power or whatever you prefer), and passing like ships in the night.

You like to talk about conservation of energy, implying that your "powerful" reflected wave model is essential to meeting the conservation of energy requirement. In fact, your model is a poster child for the violation of energy conservation. Electromagnetic energy, like any energy, is a scalar quantity, and it is only positive. It is not possible to "net" the non-zero energy contributed from your counter-traveling waves to zero. The direction of the wave propagation does not change the sign of the energy. Be careful here; energy is *not* the same as the energy flux or Poynting vector. Don't mix terms that have totally different units. What *can* be assigned negative values are the fields. (Voltage and current are not exactly "fields", but they will work for these transmission line examples.) A "net" of zero volts or current is exactly what happens at the standing wave nodes resulting from the counter-traveling waves. After you have done the superposition correctly, using fields, not energy or power, then you can easily

determine the energy and power state as needed. Conservation of energy will be automatically satisfied, assuming no mathematical blunders. The Maxwell equations would be pretty useless if they did not provide conservation of energy.

For future reference, just remember: Fields first, then power or energy. That's the way superposition really works.

I heartily second Keith's recommendations.

For some simple illustrations of one problem with chasing "power waves" around, see http://eznec.com/misc/Food_for_thought.pdf, particularly the "Forward and Reverse Power" section beginning on p. 6 and the table on p. 8. This was originally written and posted more than five years ago and, to my knowledge, the problems it raises with the concept of "power waves" still haven't been addressed in the thousands of postings on the topic in the intervening time.

It is sadly amusing that Cecil takes so much comfort in optics. The
electromagnetic theory for optics (e.g. somewhere in the vicinity of
visible light) is of course identical to the electromagnetic theory for
HF. The preferred applications and shortcuts are sometimes a bit
different, but that is simply a matter of convenience and of no
importance here.

I have a couple of editions of Born and Wolf, which is a high level reference and often considered the standard for optics. I have been unable to find even one mention of "constructive" or "destructive" interference in their writing. Of course they delve into the topic of interference in excruciating detail. They don't, however, ascribe any particular mysticism or magic to interference. It is simply what happens when the wave fields are superposed.

The more popular accounts, such as the FSU Java applet on interference, the Melles-Griot web site, and apparently the text by Hecht, stay a bit further from rigorous analysis. Therefore they resort to handwaving requirements such as destructive must be balanced by constructive, blah, blah, blah.

Adding the voltages in the manner you and Roy have done is precisely the same operation as Cecil's interference method, without the emotional baggage.

Of course you two want to deny that reflected waves
contain any energy at all. If there is any energy
in reflected waves, your house-of-cards collapses.

So Roy, please explain how all those reflected
waves that are incident upon your optic nerves
don't contain any energy. (I'm not going to hold
my breath for your answer.)

'Addition' is not a cause. What is the actual cause - i.e. what
exactly causes coax to melt at half wavelength intervals?

> real power, they cannot directly supply any real power.

To be consistent with the definitions EM waves don't actually
'contain' power, but it is certainly true that interference patterns
don't propagate and transfer energy.

Thanks Gene, I never thought you would ever admit that
fact of physics. Now that you have, your entire argument
collapses. If interference can happen in free space, it
certainly can happen in a transmission line.

> I have a couple of editions of Born and Wolf, which is a high level

Try "Optics" by Hecht. He devotes an entire chapter
to interference. Hecht mentions destructive and constructive
interference dozens of times. I can quote page after page
of such if you want me to. Feel free to dispute Hecht if
you want, but that is your problem, not mine.

> Of course they delve into the topic of

Neither do I. It is just what happens when the wave fields
are superposed. The destructive interference must balance
the constructive interference to avoid violation of the
conservation of energy principle.

Like addition, superposition is a mathematical operation. There is without question a mathematical result to most mathematical operations. But what does this operation itself actually cause in our case? A physical result has been obtained, but what is its exact cause? I don't think 'addition' is the best answer.

I'm top posting this so readers won't have to scroll down to see it, but so I can include the original posting completely as a reference.

Keith, you've presented a very good and well thought out argument. But I'm not willing to embrace it without a lot of further critical thought. Some of the things I find disturbing are:

1. There are no mathematics to quantitatively describe the phenomenon.
2. I don't understand the mechanism which causes waves to bounce.
3. No test has been proposed which gives measurable results that will be different if this phenomenon exists than if it doesn't. (I acknowledge your proposed test but don't believe it fits in this category.)
4. I'm skeptical that this mechanism wouldn't cause visible distortion when dissimilar waves collide. But without any describing mathematics or physical basis for the phenomenon, there's no way to predict what should or shouldn't occur.
5. Although the argument about no energy crossing the zero-current node is compelling, I don't feel that an adequate argument has been given to justify the wave "bouncing" theory over all other possible explanations.

None of these make an argument with your logical development, although I think I might be able to do that too. But I'm very reluctant to accept a view of wave interaction that's apparently contrary to established and completely successful theory and one, if true, might have profound effects on our understanding of how things work. So frankly I'm looking hard for a flaw in your argument. And I may have found one.

A large part of the argument seems to revolve around a single point in a perfect transmission line, where the current is exactly zero. This is an infinitesimal point on a perfect line, so some anomalous things might be expected to happen there.

Let's consider a transmission line as a huge number of series inductors and shunt capacitors, each an ideal lumped device. In the ideal case, of course, there would be an infinite number of each, and each would have an infinitesimal value. However, the LC product and ratio must remain correct even in the limiting case. Each L and C is an ideal device, so the current into one terminal of an inductor has to equal the current out of the other. A consequence of this is that either we have a whole inductor with zero current, or the zero current point occurs between inductors, at a node to which a capacitor is connected. I think we'll get the same result using either scenario, but let's consider the second.

If we analyze this situation carefully, we'll find that the inductor on each side of the zero-current point does have a finite current, equal in

amplitude and flowing in opposite directions. So for half of the cycle, both are putting positive charge in the capacitor, and for the other half of the cycle, both are removing charge. The capacitor voltage goes up and down as a result, as we can also see by looking at the voltage at this zero-current point. So current from both sides is contributing to the capacitor charge, and turning off either one would change the line conditions. Any change in the current from the inductor on one side would change the capacitor voltage, and hence the current on the other side. So there is an interchange of information from one side to the other. Each inductor is conveying energy to the capacitor, which is storing and returning it.

Ok, so let's break the capacitor into two, each being half the original value, and constrain each inductor to deliver charge only to "its" capacitor. The wire between the capacitors carries no current because the capacitors always have equal voltages, and can be cut with no effect.

When there was one capacitor, it shared energy from both sides. When we broke it into two, there was no mixing of energy from either side. Why might one be a better description of reality than the other? It looks to me like the argument devolves into speculation about how small the "point" is at which the current drops to zero.

It would be instructive to see what happens as, for example, the load resistance is increased toward infinity or decreased toward zero arbitrarily closely, but not at the point at which it's actually there. If the "bouncing" phenomenon is necessary only to explain the limiting case of infinite SWR on a perfect line but no others, then an argument can be made that it's not necessary at all. I suspect this is the case.

I agree with your argument about two sources energized in turn, and have used that argument a number of times myself to refute the notion of superposing powers. Once two voltage or current waves occupy the same space, the only reality is the sum. We're free to split them up into traveling waves or any other combination we might dream up, with the sole requirement being that the sum of all our creations equals the correct total. (And the behavior of waves you're describing seemingly go beyond this.) The advantage to the non-interacting traveling wave model is that it so neatly predicts transient phenomena such as TDR and run-up to steady state. I spent a number of years designing TDR circuitry, interfacing with customers, and on several occasions developing and teaching classes on TDR techniques, without ever encountering any phenomena requiring explanations beyond classical traveling wave theory. So you can understand my reluctance to embrace it based on a problem with energy transfer across a single infinitesimal point in an ideal line.

I proposed this some time ago, and got the response that dissimilar pulses would still bounce off each other, yet appear exactly as though they were passing through without interaction. I haven't been able to understand why this would be, but there are no mathematics to explain it.

Or so it might seem to someone who had neglected to consider that the
'per second' in Joules per second in this case derives from the rate
at which charge is moving.

> 2. I don't understand the mechanism which causes waves to bounce.

If I might amplify a similar concern.

Bounce is a phenomenon in everbody's experience, hence the term easily clouds the conversation as it also not a very rigorous term in RF.

In the day to day world of, say, rubber balls, bounce implies:
1. an inelastic deformation upon collision;
2. the conversion of kinematic energy into potential energy;
3. a period or interval of holding that potential energy (or further accumulation of potential energy);
4. the cessation of the inelastic deformation and the rebound unwinding 1-3 above as potential energy is converted back into kinematic energy.

So, for this "bounce" in a wave, can I observe the inelastic deformation? (Not just the superposition of waves, but the actual inelastic crush against resistance.) Inelastic often has loss attending it, do you care to characterize it as elastic? If so, then the usage of "bounce" is running against the grain of popular usage.

In this "bounce" in a wave, can I observe the time interval during which kinematic energy is converted to potential energy and then back to kinematic energy? (Is there a retardation in the wave migration? I would suspect a phase change might reveal this, and not just a phase inversion, nor a phase reversal.)

I guess I must be hitting close to target. You always get nasty when I create problems for your pet theories.

Thanks for the reference to AN 95-1, even though I have several copies already. Your directed search terms prove my point exactly. I suppose puncturing your balloon is "unethical", but that is your problem, not mine.

I challenged you to find any case in AN 95-1 that supports your claim of counter-traveling waves in a transmission line, with each wave carrying its own energy that somehow nets out to zero. You came up with exactly nothing, which is not surprising.

Ranting and raving does not have any impact on the correct physical reality.

Oh, by the way, my full comment was, ". . . there is no mention of incident and reflected waves on a transmission line, each carrying energy (or power or whatever you prefer), and passing like ships in the night."

Your careful trimming is noted.

As you have stated before, the standing wave is the ENVELOPE of maxima resulting from forward and reflected waves. The ENVELOPE maxima and minima will occur at 1/2WL distances in the cable. If the line is lossless, no power is consumed in the unterminated line.

If I were to see a cable with melted insultion at 1/2 wavelengths and the coax was open, the first thing I would suspect is that the voltage on the inner conductor greatly exceed the dilectric strength of the insulation between inner conductor and shield at the original standing wave maxima and minima. Two 3-500Z's in series could produce 6KV or even more. Standard Radio Shack grade RG58 might not be able to handle that. When the insulation breaks down it turns into a carbon resistor and we no longer have a lossless situation; real power is dissipated. Whther or ot the standing wave is still present, power will dissipate where the dielctric material has turned into carbon (even with DC). Less likely would be current heating the inner conductor, again a resistive power loss. But these discussions have been assuming a lossless line of infinite dielectric strength where real power disspiation cannot occur unless we terminate the line and only then, in the terminating component since the line is supposedly 'lossless'. Adding the real life burnt coax example when the discussion assumes ideal components is comparimg apples and oranges; all we are doing is exposing the weakness of the assumption when using ideal lossless components. BTW, in any case in which insulation melting occurs and we have deviated from the ideal transmission line, at least some of the reactive power that was contained in the standing wave has now been changed into a travelling wave with I/V in phase thru the 'resistors' between inner conductor and shield.

> the current into one terminal of an inductor has to equal the current
> out of the other.

That is not correct. If both the capacitor and the inductance are
ideal

they cannot return the same amount of energy. This can only happen
when the
summation of all vectors are parallel to the axis of the conductor.
One only has to look at the vectors involved with out assigning length
to the vectors to see that the vectorial summation cannot be parallel
to the radiator axis. This is exactly why for maximum horizontal gain
the radiator is tipped away from the earth's surface. This response
is clearly shown when a time varient is added to Gaussian law.

A consequence of this is that either we have a whole
> inductor with zero current, or the zero current point occurs between
> inductors, at a node to which a capacitor is connected. I think we'll

> half of the cycle, both are removing charge.

That can only be true for a full wave radiator which emulates
a tank circuit. A half wave radiator is a series circuit,
a whole different ball game !

The capacitor voltage goes
> up and down as a result, as we can also see by looking at the voltage at

Not at the change over point where voltages are equal since a
capacitor
has a slight delay before discharging because of initial inductance
delay.

Any change in the current from the inductor on one side
> would change the capacitor voltage, and hence the current on the other

It takes energy to propagate does it not?
Why would you ignore that?
>

Again that cannot be. The filling of all the capacitors fill up in a
series format.

I did exactly that earlier and you didn't comprehend
it then - but here it is again.

(b1)^2 = (s11*a1 + s12*a2)^2 = 0

(b1)^2 is reflected power. It is only zero when
(s11*a1 + s12*a2)^2 = 0

(b1)^2 = (s11*a1)^2 + (s12*a2)^2 + 2(s11*a1)(s12*a2)

Since a1 and a2 are phasors, their multiplication
involves cos(A) of the Angle between them.

Pref1 = P1 + P2 + 2*SQRT(P1*P2)cos(A)

Does that equation look familiar? Please reference the
s-parameter ap note, pages 16 & 17, for the meaning of
those squared terms. The power density equation can be
derived from the s-parameter equation.

Since the reflected wave is reflected, the reflection
coefficient cannot be zero.

If the reflected wave is not reflected, there
would exist current in the source, but there
is none.

There are no references for pathological thinking.

The example was carefully chosen to illustrate the
point, of course. But that is the value of particular
examples.

When the pulses are not identical, the energy that crosses
the point is exactly sufficient to turn one pulse
into the other. The remainder of the energy must bounce
because it does not cross the mid-point.

> 73, Cecil http://www.w5dxp.com

Cecil,
All of the bickering come to a halt if you consider a full wave
radiator
instead of a half wave antenna. Yes, both can be resonant but only
one is in a state of equilibrium. The underpinnings of all laws
whether
mechanical or electrical is that all is in a state of equilibrium
otherwise the laws do not apply.
When there is a state of equilibrium one cannot have a collision of
waves.
The sequence for equilibrium is a magnetic field followed by a
electric field
which equals one period. Sloshing is a poor word. When current is
moving forward
you are charging up the `capacitor when the current changes direction
the capacitor
discharges as if it was shorted and creates a near instantaneous
electrostatic field
which dissapates while charging up the inductance which is also the
transition of
generating a magnetic field around the inductance.
During this time there is also a side ways force that affects or
depletes the current
by deflection which allows for propagation.This force is what is
termed "curl"
amongst many other names
At no time are there any counter waves because, not only are we
resonant but
we are also in a state of equilibrium. Move away from a fractional
wavelength
to a full wave length so both sides starts from a common point ie
resonant
and in a state of equilibrium and your difference will then be
resolved quickly.
Hope the above helps to stop posters from talking past each other.

My best regards
Art Unwin KB9MZ....XG(UK)

Keith, your model is not realistic. As you know, any signal you impose on a conductor will form an electromagnetic wave. This is the combination of electrostatic and electromagnetic fields, and it propagates at the normal velocity for that medium.

However, electromagnetic waves do not interact with each other, and they cannot bounce off each other.

Recall that light from stars is electromagnetic. It travels many light-years before it reaches your eyes. If electromagnetic waves interacted, you would not be able to see individual stars - they would merge into a blur.

Similarly, the signals reaching your antenna and traveling down the coax to your receiver do not interact with each other. As long as your receiver is not overloaded, the signals remain separate no matter how many stations are on the air at the moment.

So the statement that like charges repel does not apply to electromagnetic waves, and the pulses cannot bounce off each other.

Regards,

Mike Monett

Ummm, Dan, as this is an explicitly new thread (purposely so to gouge this thumb into the ideal eye) with such an intro as you are responding to...
We are not in Kansas any more.

Jim's question is answered quite simply and you have offered one yourself, generously slathered with doubt about its obvious application.

However, my guess finds the symptoms would be more aligned with two current nodes, not voltage. However, voltage or current, either mock the notion of "traveling waves," as Cecil recoils in shock from the bitter reality (his bï¿½te noire when it fails to serve his agenda) of this contradiction.

It relates to another bitter round in his own thread of trying to explain the confusion Hams have with Rhombic antennas and traveling waves to then discover standing waves line up and down them:
On Wed, 02 Jan 2008 21:19:53 GMT, Cecil Moore <nospam@w5dxp.com> wrote:
>Ideal traveling-wave antennas have no standing waves.

Formula:
1. The guru starts to resolve the confusion about real traveling wave antennas to the assembled unwashed masses;
2. a voice pipes up with simple data showing standing waves on real traveling wave antennas;
3. the guru abandons the explanation to resolve the confusion about real traveling wave antennas;
4. the guru denounces real traveling wave antennas as being non-ideal.

I get a kick out of Cecil, really. The built in failures of his arguments are so scripted that mocking them is like writing for the sit-com where Dick Van Dyke forever trips over the ottoman.

Should read

vtot(t, x)(steady state) = (sin(wt - x) + sin(wt + x)) / (1 - 0.5) = 2
* (sin(wt - x) + sin(wt + x))

This was a typo and has no effect on the steps which follow or the
conclusions.

Thanks very much to the kind person who brought this error to my attention.

The last sentence should read:

Since the line initially presents an impedance of Z0, this should also
be Vin(rms)^2 / Z0 or Iin(rms)^2 * Z0. . . .

The calculations which follow were done using the correct formula, so
the mistake had no effect on the following steps or the conclusions.

I also carelessly and incorrectly used j as an abbreviation for joules
throughout the posting. The correct abbreviation is J. (And yes, the
name of the unit is correctly joule, not capitalized, as is the case for
most if not all SI units named after people.) This mistake is made
potentially worse because of the possible confusion with the imaginary
operator j (as used by electrical engineers). I apologize for any
confusion the mistake might have caused.

Thanks very much to the careful and thoughtful reader who brought these
errors to my attention.

Mike
They will not listen to you because they are following books that are
incorrect.
They cannot get into their minds that for a given frequency the time
for
a cycle is always the same. And as I have pointed out many times in
different ways
that goes for 1/2 wave antennas too.
If one bends a half wave antenna such that the ends are close together
you
can feed at the wire ends.
So now you apply a DC current at one end and it will continue to go
forward
all the way to the other end of the wire.Wen it gets to the end of the
wire
the current reverses direction and goes back to the starting point
which
completes one wave length of travel which also represents one
wavelength of time.
Now the other side of the debate wants a half wave antenna.So let us
lay
that half wave antenna out in a similar way that we bent the half wave
length
antenna
Start a DC current at one end and it travels to the other end of the
wire
BUT TIME HAS NOT RUN OUT FOR FLOW IN THE SAME DIRECTION,and this is
the
crux of the debate since the current still has to move forward and
thus
can only procede down the center of the wire .
IT CANNOT GO BACK AT THIS TIME.
The time for forward travel runs out when it gets to the end of the
wire.
When time runs out it reverses direction and goes back up the inside
of
the wire and down the outside of the wire to the end or shall we say
return to the beginning to complete the cycle.
It can be seen that with a half wave antenna the current flows on the
surface
only half of the time such that it only encounters inductance and
capacitance
for half of a cycle such that it can radiate. The rest of the time
because
the current flow is not exposed to the surface it does not radiate.

At no time is the current going two different ways.
Unfortunately people ignore the requirements of time and for some reason want to change current direction to half the time required for that frequency thus creating collisions in the current flow. THIS DOES NOT HAPPEN. So gentlemen layout a bent full wave antenna and along side it lay out a half wave antenna in the same fashion and start current flow in both at the same time where length of travel is commensurate with time. You will now realise that all participants in this debate have been talking past each other.
Another way of looking at it is to draw a full wave length of communicationline in ladder form with its component inductances and capacitances. One side of the ladder drawn line has zero energy storage components only resistance and it is this line that represents travel down the center of the wire.
The bottom line is that a half wavelength antenna represents a full cycle with respect to frequency.
This will be the last time that I will try to explain the radiation characteristics of a antenna.
Best regards to all

I am suprised that a book on optics would discuss the
output impedance of Thevenin equivalent circuits.

Be that as it may, could you kindly provide the brief
extract from "Optics", by Hecht, that clearly states
that the impedance in a Thevenin equivalent circuit
can not be used to compute the reflection coefficient.

So it is stored only in the E field. Is it an
EM wave when only an E field is present?

> 2. The LCLCLC transmission line model - the energy
> is alternately stored in the L's and C's.

Since there is no current, it is stored only in
the capacitance of the line.

> 3. The Sloshing Model - I'll let Roy handle that one.

The sloshing has stopped, so the answer is the same
as 2.

But the important question is: Do you consider it
to be an EM wave when only an E field is present?

I fully agree with the philosophy you express here Keith. But I can see how you would doubt that I am practicing what I just agreed with.

You have posted several times on the subject of impedance of an ideal source, and I have learned from your words. You may find however, that I have still not completely grasped an important component of the concept. If that happens, please try again, using a different argument.

Learning is a meshing of words, ideas, concepts, experience, and more. You can see that I am inexperienced. I can see that many of the posters are very experienced. Experience is not necessary for presenting an argument, but it certainly helps in presenting the argument wisely, coherently, and convincingly. Correctness is always a judgment by the reader.

Some time ago JS woundered why we view the center of the earth is not represented by force vectors
pushing OUT ie the equal and opposite reaction with respect to gravity. This is a very insightful comment.
In fact the earth's ferrite mass center is represented by the magnetic poles but because of the diagmagnetic content of the earth which produces a weak magnetic field at right angles to a ferrite field we have two magnetic axis at a distance from each other in our earth and not just one.Thus somewhere, in between these two pole structures, we have a point of equilibrium where the vector forces emminate from this point in a outward direction. It is the position of the diagmatic pole that provides the "curl" effect as seen when studying the radiator vector format which is also responsible for the earth turning and the circular rotation of a pendulum to which a radiator is often compared..
(By another name I believe this also describes the Corriolis effect)
One can stretch their minds and ponder on the effect of this diamagnetic pole tho weak would have on a compass on opposite sides of the earth, such as the Bermuda triangle and the area on the other side of the earth but of to the side where Amelia Erhardt altered her course for a unknown reason and disappeared.

> Roy Lewallen, W7EL

By my using the words 'power' "storage factor", you got my point, hence
the reaction.

Before dismissing the concept of "storing power", consider that when
discussing a transmission line, it could be a useful description.

As you know, power is energy delivered over a time period. It always
carries a time dimension having beginning and end. Power(watt)
=v*i/(unit time) = 1 joule/second.

In the example you give of charging a capacitor, the time dimension is lost, so you are correct that only energy is conserved. Power is lost.

With a transmission line, we have an entirely different case. Here power is conserved because the time information is maintained. Power is stored on the line during the period it resides on the line. For example, we excite the line at one end and some time period later find that power is delivered to some destination. During the time period that the power was on the line, the information that defines the energy distribution over time has been preserved.

If power is stored, we implicitly store energy. Energy is v*i measured in joules without a time factor. Obviously we store energy on a transmission line when we store power.

So if in the future, I use the term "power storage", please take it to mean that energy distributed over time is under consideration. I hope the term might be useful to you as well.

This would seem to me to depend on the nature of the
interaction. Clearly the interaction represented by
the term "bounce" (for lack of a better word) would
have to be such as to not violate any of these
observed behaviours.

> Similarly, the signals reaching your antenna and traveling down the

> electromagnetic waves,

Q1. Are you saying that it is inappropriate to view
a transmission line as distributed capacitance and
inductance and analyze its behaviour using charge
stored in the capacitance and moving in the
inducatance?

If such analysis is appropriate, then it seems
to me that a pulse can be viewed as a chunk of
charge moving down the line.

Q2. Is this an appropriate view?

Q3. If so, then what happens when two such chunks
of charge collide in the middle of the line?

The existing analysis techniques tell us that
no current ever flows at the mid-point of the
line, this means no charge crosses the mid-point.

Q4. Is this correct?

Q5. If no charge crosses the mid-point, then how
do the pulses, made up of chunks of charge.
pass the mid-point?

Q6. If they do not pass the mid-point, then what
happens to them?

I have offerred a somewhat intuitive explanation.
Other explanations are welcome.

Any explanation that does not involve charge will
immediately cause me to ask Q1 again.

You may have mis-interpreted my comments. I have NOT
seen evidenace of the behaviour I describe above in
your writings.

The comments mostly apply to a single poster who has
been posting on this group for many years, at least
since when I first started viewing this group in the
mid 90s and began to really gain an understanding of
transmission lines.

The presence of this poster providing misleading
information makes this group a rather unique learning
environment.

In most learning environments, the information is
neatly packaged and presented from a consistent
point of view with no challenge.

Here, a lot of chaff is mixed with the wheat. This
has the "benefit" of forcing the learner to
understand well enough to make decisions between
competing explanations. The learner who makes the
right choices comes out with a much more solid
understanding than one who has just been (spoon)

fed the story. On the other hand, some have probably been lead seriously astray.

For sure, I have a better understanding than I would have had without the challenging misleading information.

So for sure it would be better for the poster in question were he to let go of some of his incorrect beliefs, it would also reduce some of the opportunities for learning provided to others lurking or partaking in the discussions.

The term "bounce" means they interact. Electromagnetic signals do
not interact. They superimpose. Each is completely unaware and
unaffected by the other.

>> Similarly, the signals reaching your antenna and traveling down

No. You need to include the associated magnetic field.

> Q3. If so, then what happens when two such chunks of charge
> collide in the middle of the line?

Electromagnetic signals do not collide. They superimpose.

> The existing analysis techniques tell us that no current ever
> flows at the mid-point of the line, this means no charge crosses
> the mid-point.

> Q4. Is this correct?

That statement has no meaning.

> Q5. If no charge crosses the mid-point, then how do the pulses,
> made up of chunks of charge. pass the mid-point?

The pulses are not chunks of charge. They are the combination of
electrostatic and electromagnetic fields. You cannot separate the
two.

> Q6. If they do not pass the mid-point, then what happens to them?

That statement has no meaning.

> I have offerred a somewhat intuitive explanation.

Your explanation does not work.

All you have proved is that you cannot tell one photon
from another. Your whole charge repulsion argument
falls apart when dealing with photons (which constitute
EM waves). I suggest you study and discover what is
possible with photons and what is not possible. You
seem to be concentrating on the carriers of the waves
rather than the EM waves themselves. Photons do NOT
and cannot bounce off of each other under ordinary
circumstances. You are simply illustrating the limitations
of ignoring the basic physics of the situation and wasting
a lot of time and effort in the process.

I have sat on a cliff overlooking the Pacific Ocean
at Fitzgerald's Marine Reserve north of Santa Cruz, CA
and have seen waves rolling in, reflecting off the beach,
and rolling back out to sea. Those waves pass through
each other as if the other wasn't there. The wave energy
is moving in both directions. The H2O carriers move
hardly at all. You can argue that the energy in the
waves is equal and therefore no average energy is being
transferred, but I still see the waves with people
riding on those waves. I do not see waves bouncing off
of each other although one could, as you have, delude
oneself into creating a mental illusion of such.

When I look out into my back yard, I am seeing reflections.
If there were a thousand people here, they would all be
seeing different reflections all passing through each other.
Photonic waves pass through each other unimpeded. It would
be a weird looking world if they bounced off each other.

In a wire, photons do not bounce off each other. However,
superposition can cause a redistribution of photon energy
at an impedance discontinuity. We call that redistribution
of energy a "reflections".

The above is correct omly when the mid point you are refering to
is at the point where the time to complete half a peried is reached.
On a half period length that is at the end of a half wave radiator
the return path is the second half.The ant6enna only radiates
when the current travels on the surface towards the inductance
when the capacitors are discharging
Physical radiator length is half a cycle or period because half
the time it is travelling forward and the rest of the time backwards.
Hams must stop equating antenna length with a full wave length,
it equates to half a wave length. It is obvious then that the
completion of a cycle thus at no time has current moving
other than a single direction. Until hams get this distinction
into their heads they will never understand radiation.

You did not directly answer Q1, but I take if from all the other responses that you are saying the answer is "no, it is not appropriate to view a transmission line as distributed capacitance and inductance and analyze its behaviour using charge stored in the capacitance and moving in the inducatance?"

Taking this invalidates all the subsequent questions since they are based on the premise that this kind of analysis is appropriate.

Or have I misinterpreted and your only concern with Q1 was that I did not mention that energy is stored in the electric field created by charge in the capacitance and the magnetic created by charge flowing in the inductance?

Mike, can we add "do not interact with each other" in
an unchanging medium? Coherent waves can apparently
interact at a change in mediums (impedance discontinuity).

One of the s-parameter equations illustrates that apparent
fact.

b1 = s11*a1 + s12*a2 = 0

Assuming a1 and a2 are non-zero forward and non-zero reflected
voltages, the only way they could superpose to zero is to
interact at the impedance discontinuity.

EM fields act that same as static magnetic fields.

Why not just get some iron filings, a paper and a couple of magnets?

Move the magnets about below the paper with the iron filings above and actually get a visual on some magnetic fields and how they react to each other?

I like things simple ... then the math can follow ...

Anyone following this thread knows that the above is absolutely
false. It is akin to dismissing lossless line analysis because
lossless lines don't exist in reality.

It is true that most real world standing wave antennas also
possess traveling waves. When an antenna is 90% standing waves,
the current on the antenna is primarily standing wave current
with a phase that changes very little end to end. The traveling
wave current is almost invisible.

It is true that most real world traveling wave antennas also
possess standing waves. When an antenna is 90% traveling waves,
the current on the antenna is primarily traveling wave current
with a phase that changes with length. The standing wave current
is almost invisible.

Richard is either very confused himself or deliberately trying
to confuse others. Each reader can decide for him/herself.

The "Optics", by Hecht reference is for destructive
and constructive interference, not Thevenin equivalent
circuits, but your attempt to confuse everyone is noted.
"Thevenin" is not even in the index of "Optics" so your
attempted diversion is ridiculous on the face of it.

I will repeat an earlier posting that you conveniently
chose to ignore. If we measure the forward power and
reflected power with a Bird wattmeter at the output of
your source during steady-state, it will tell you that:

forward power = reflected power

From that we can calculate the reflection coefficient.

rho = SQRT(Pref/Pfor) = plus or minus 1.0

Can photons explain the state of a transmission
line driven with a step function after the line
has settled to a constant voltage?

If not, there would seem to be some difficulty
with the applicability.

Excellent. So there is NO reference that claims
that the output impedance can not be used to
compute the reflection coefficient.

There are many references that do.

So that settles it, then. Many references on one side,
none on the other. It is time for you to accept the
standard methodology for computing the reflection
coefficient at a generator. And no, I am not holding
my breath while I wait.

And the arguments that I have seen between Mr. Maxwell
and Dr. Bruene are on a completely different matter.

Keith wrote:
"I am surprised that a book on optics would discuss the output impedance of Thevenin`s equivalent circuits."

Hecht is a physicist.

On page 74 of Terman`s 1955 0pus, he writes:
"According to Thevenin`s theorem, any linear network containing one or more sources of voltage and having two terminals behaves, in so far as a load impedance connected across these terminals is concerned, as though the network and its generators were equivalent to a simple generator having an internal impedance Z and a generated voltage E, where E is the voltage that appears across the terminals when no load is connected and Z is the impedance that is measured between the terminals when all sources of voltage are short-circuited."

On page 87 of his 1955 opus, Terman writes:
"The vector ratio of E2/E1 of the voltage of the reflected wave to the voltage of the incident wave at the load is termed the "reflection coefficient" of the load."

On page 97, Terman writes:
"The standing-wave ratio S is one means of expressing the magnitude of the reflection coefficient;"

On page 214 of "Schaum`s Outline of College Physics", Bueche & Hecht write:
"Standing waves---These might better not be called waves at all since they do not transport energy and momentum.---"

Cecil is vindicated.

Best regards, Richard Harrison, KB5WZI

My attempt to confuse!? We were discussing the determination
of reflection coefficients for Thevenin equivalent circuits.

But in another post, you have agreed that there
is a complete lack of references supporting your
position, so the question is now settled and you
can use the standard methodology to compute
reflection coefficient at a generator where
the output impedance is well defined.

Enjoy the new ability to solve problems that
were previously outside your grasp.

Wrong! Please reference a book on EM waves. An
EM wave CANNOT have a stationary E-field in an
ordinary transmission line or in free space.

> But the important question is: Do you consider it
> to be an EM wave when only an E field is present?

No, that violates the definition of an EM wave. If
only an E-field is present in a transmission line or
in free space, it is NOT an EM wave, by definition.

For a single EM wave to exhibit a zero H-field, the
Z0 would have to be infinite which is clearly impossible
for free space or ordinary transmission lines.

Good answers. Exactly as I expected. Now please
explain the applicability of EM waves to the
state of an open circuited line excited with a
step function, especially after it settles to a
constant voltage (where only an E field will be
present).

Q5."If no charge crosses the mid-point, then how do the pulses, made up of charge, pass the mid-point?"

Radio waves propagate through empty space. No charges are needed for propagation, but a wire contains free electrons which are urged to move in-synch by a passing wave. That does not mean they migrate. In the wire, electrons go nowhere fast. Their motion is mostly in-place. It the energy which is traveling, not the electrons.

Best regards, Richard Harrison, KB5WZI

Yes, it does.

Your explanation is easily proven false. Let's suppose it was true.

Suppose it was possible to introduce a pulse of charge onto a
conductor.

Since like charges repel each other, what keeps the pulse together?

In other words, what prevents it from destroying itself?

Then, when the first pulse meets the second, what mechanism allows
them to bounce off each other?

Then, after they have bounced off each other, what mechanism keeps
them together?

But a learning experience nonetheless. All one has
to do regarding false information is to produce
valid technical references to the contrary.

Ad hominem attacks are not technical references
and the mere assertion that the information is
misleading implies some level of omniscience in
the asserter that is not in evidence.

For the record: The only controversial assertion
that I have ever made is that coherent EM wave
cancellation can cause a redistribution of the
EM energy in the opposite direction in a transmission
line. No one has proved that assertion to be wrong.

A couple of technical web pages assert that wave
cancellation can be the cause of a redistribution
of photonic energy to areas that allow constructive
interference.

Since there is only one other direction available
in a transmission line, the constructive interference
must occur in the opposite direction from the
direction of wave cancellation.

That seems like a no-brainer to me.

John, There is no way you have a standing wave. I know the books
suggest
that but the books are wrong. When current gets to the top of a
fractional
wave antenna it just does not turn back. It has to wait until half a
period time has
elapsed The turning around point is determined by frequency and
frequency alone regardles of the length of the radiator. I f the
forward time has not run out the current must continue going forward
and that means going down the center of the wire which is resistive
only and does not generate radiation. The current traverses the center
twice and it is when it starts to return on the outside is when
propagation comences. So at no time is the current changing direction
except at a time of half a period. It only has one pulse per period
and that pulse is dependent on the surface content that it traverses.
If it is a full wave where the length equates to half a period then
the capacitance and inductance is comensurate with length.

If it is a fractional wavelength it only radiates when returning on the surface where the energy storage content is half that of a full wave
This particular point has arrested the advances in antennas for 100 years just because man does not accept change.
Regards
Art

> unaffected by the other.

Except when they are coherent, collinear in the same direction,
equal in magnitude and 180 degrees out of phase. Thensomething
permanent happens as signified by the s-parameter equation.

b1 = s11*a1 + s12*a2 = 0

s11*a1 and s12*a2 are coherent, collinear in the same
direction, equal in magnitude and 180 degrees out of
phase. Their combined energy components are redistributed
in the direction of b2 = s21*a1 + s22*a2

Squaring the above equation results in the power density
irradiance equation from the field of optics.

Preflected = (b1)^2 = (s11*a1)^2 + (s12*a2)^2 + 2*s11*a1*s12*a2 = 0

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that
are 180-degrees ... out of phase with each other meet, ...
All of the photon energy present in these waves must somehow be
recovered or redistributed in a new direction, according to the
law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, ..."

That certainly sounds like an "interaction" to me.

I see your example as identical to Keith's example of two wave pulses traveling in opposite directions.

At the point of interaction, Keith's example has a reflection factor of 1 or zero, depending upon whether the waves bounce or pass. Keith's example is not a short circuit because two pulses of identical polarity are interacting so a reflection factor of -1 could never exist.

In your example, the presence of voltage from the ideal source creates conditions identical to Keith's example for the returning reflected wave. Accepting this premise, then the reflection factor must be either 1 or zero, depending upon whether the waves bounce or pass.

By assuming that the waves reflect at the ideal source, you proved that the reflection factor is -1, which is the factor for a short circuit. This can not be the case, so waves must not reflect at the ideal voltage source, they must pass.

vtot(t, 0) = vf(t, 0) + vr(t, 0)

= sin(wt)tot = sin(wt) + sin(wt)

= 2*sin(wt)

Someone will certainly say the the vtot(t,0) at the source location is the source voltage, because it is defined that way. The conditions at point (t,0) itself is actually unknown (because vf mysteriously appears, and vr disappears by going off the transmission line), but point (t, >0) is defined by assumptions. Therefore, at

vtot(t, >0) = vf(t, >0) + vr(t, >0)

= sin(wt)tot = sin(wt) + sin(wt)

= 2*sin(wt)

Of course, photons can be used to explain all
EM wave action. A step function accelerates
electrons which then emit photons as EM waves.
Hint: electrons cannot move at the speed of
light. EM waves move at the speed of light.

Hi Dave,

I am well practiced mixing it up with the masters of obscurity, and I certainly don't confuse you with Prior Art, or Cecileo. However, the HVDC project you allude to is new to me (even if it is/was decades old).

As an aside, I have worked with the lawyer who was instrumental in closing down WPPS (a nuclear power consortium we generally called WHOOPS). That consortium agonized that Washington's credit rating would go down the toilet if we defaulted - barely a blip in the interest rate resulted when we mothballed several nuclear reactors.

Even further aside, I lived in Japan in the early 50s when they used DC residential power (and we had to be careful to buy AC/DC appliances). Woe to those living at the end of the block where the street lights were dim.

Edison used to portray AC as being the killer current (eventually selected for use on death row). Actually there were a mix of characteristics that lent either the death potentiality. DC will cause the muscles to clamp, and if you seized a hazardous wire, you could never let go. AC, on the other hand (no pun), would cause fibrillation, and you stood some chance of releasing the same hazardous wire. AC, on the third hand (again, no pun), would also cause the sweat glands to excrete (due to the same fibrillation) and lower your path resistance (more lethal current).

Cecil
The current only changes direction at the behest
of the frequency. I know you think that the
current changes at the behest of the
length of radiator used i.e. at the top but
frankly that is lunacy. It is only when the capacitor charge
starts to move to the inductance and starts to store energy
which generates a diamagnetic field can propagation can occur
You must get a pencil and paper and think things out for
yourself instead of relying on books. With your IQ it should
be a cake walk because unlike some others you are able to get
back to first principles instead of learning by rote.
No personal offence intended. Being stubborn is not all that bad
but only if you are willing to think out alternatives given.
Otherwise it is a not invented in my back yard aproach which
amounts to an over inflation of one's ability
Best regards
Art

> ...Keith

So it really is almost as though the pulses travel through one another, rather than bounce off one another.

I have seen the concept that energy doesn't cross nodal points alluded to in some texts. However there are so many exceptions to it found in physical systems as to render it a dubious notion at best. Useful perhaps for illustration purposes.

In the discussion of standing waves on a string, Halliday and Resnick says "It is clear that energy is not transported along the string to the right or to the left, for energy cannot flow past the nodal points in the string, which are permanently at rest. Hence the energy remains "standing" in the string, although it alternates between vibrational kinetic energy and elastic potential energy."

So the idea is valid for a simple harmonic oscillator in which there are no losses. In such a case, once the system begins oscillating, no further input of energy is required in order to maintain oscillation. Clearly there is no flow of energy into or out of such a system. What is clear is that energy doesn't pass through the nodes. It is less clear that there exists an inherent mechanism which prevents the movement of energy.

And so it appears in cases where there is no transfer of energy that one might claim that waves bounce off of one another. There are no other examples, and no supporting mechanism for it of which I am aware, and so one might be equally justified in claiming that waves pass through each other in all cases.

Before it settles to a constant voltage, there is
acceleration of electrons that results in an EM
photonic wave.

After it settles to a constant voltage, there is
no acceleration of electrons and the EM photonic
wave disappears.

Please see Maxwell's equations for further
enlightenment.

I was hoping to get Cecil to think a bit more carefully about what he
has been saying. To provide quality, as well as quantity.

Hi Keith,

By a certain opaque style of writing, the tenor of questions offered,
and an aversion to to deliberating the evidence given in response; I
would say the crown of Trolling is being challenged and Cecil may slip
beneath a new prince's claim.

So when the edge of the step is travelling towards
the right, is there an EM wave to the right of the
step, to left of the step, at the step, or all three?
Similar question for when the step is travelling
back to the generator?

When the line has settled, how do you add the forward
and reflected wave to compute the voltage on the line,
or does the disappearance of the wave mean this is
now impossible?

If only the step itself has an EM wave, how are
voltages computed using reflection coefficient after
the step has reflected from the open end?

Thanks Keith. I am learning a tremendous amount here. As you say, the interaction really helps focus, reason, and justify, and finally, readjust thinking as understanding improves.

I certainly like your example of two opposite traveling pulses. I used it again today in a posting responding to Roy.

Photons are emitted and absorbed by the electrons
as the electrons lose/gain energy. Photons are not
conserved. Only the energy in photons is conserved.

In a DC system with no accelerating or decelerating
electrons, all of the photons have been absorbed
back into the electrons (or lost to radiation).
Of course, this describes an ideal system.

Of course. With one side of the Bird wattmeter
left open, it will happily measure the reflection
coefficient of that open. This says nothing about
the reflection coefficient of the line connection
with the source.

What an ego to rush to slip into a TNT vest in the hope of being
associated with Nobel.

As usual, Cecil's arguments are so script driven, that I cannot pass
up this mocking opportunity:

I shall assert that coherent EM wave cancellation can not cause a
redistribution of the EM energy in the opposite direction in a
transmission line.

No one has proved that assertion to be wrong.

Does that misleading statement qualify me for Keith's anointed villain
of the group? Cecil certainly has described me as being scurrilous
enough to so qualify! ;-)

Besides, I think I look better in that vest than he does.

Just a minute. What about the proof I offered
that the actual reflection coefficient is 1.0
based on Bird wattmeter readings?

The Bird tells us that at the source terminals,
the forward power equals the reflected power.
rho = SQRT(Pref/Pfor) = plus or minus 1.0

You are confusing cause and effect. There is an EM
wave wherever there are photons being exchanged
among the electrons. Any speed-of-light movement
is evidence of the existence of photons.

> When the line has settled, how do you add the forward
> and reflected wave to compute the voltage on the line,

After all the photons have been absorbed or radiated,
there is no forward EM wave or reflected EM wave.
They simply cease to exist in the DC steady-state
where electrons are not being accelerated or
decelerated.

> If only the step itself has an EM wave, how are
> voltages computed using reflection coefficient after
> the step has reflected from the open end?

If the step is reflected, the reflection consists
of photons. As long as anything is flowing at the
speed of light in the medium, photons exist.

Any way you choose to look at the example, the same
amount of joules are flowing into the source as are
flowing out of the source during any particular time
period. That is a power reflection coefficient of 1.0
Take the square root to find the voltage reflection
coefficient of plus or minus 1.0

The Melles-Groit and FSU web pages certainly seem to
disagree with you. To the best of my knowledge, they
prove your assertion to be wrong and support my
contention of redistribution of energy after wave
cancellation.

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and
the thickness of the film are such that a phase difference
exists between reflections of p, then reflected wavefronts
interfere destructively, and overall reflected intensity is
a minimum. If the two reflections are of equal amplitude,
then this amplitude (and hence intensity) minimum will be
zero." (Referring to 1/4 wavelength thin films.)

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as enhanced intensity in the transmitted beam.
The sum of the reflected and transmitted beam intensities is
always equal to the incident intensity. This important fact
has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit

constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

In an RF transmission line, since there are only two possible
directions, the only "regions that permit constructive interference"
at an impedance discontinuity is the opposite direction from the

direction of destructive interference.

Fortunately idiots such as you are not able to debate civily
so what you think doesn't count.You may have been a good sailor
man but without a degree in engineering you will never be able
to understand first principals. Time and time again your questions
given but no technical answers provided other than taunts is
enought to show what a miserable man you are. For a person not
to understand that a time variable added to Gaussian law
equals Maxwell's lawa plus argueing about same with a man with
a doctorate who works for the space agency at MIT shows just how
much your ego has been inflated. You are just a large inflated
ballon looking for somebody who will place a prick in you.
Begone you miserable urchin.

Art wrote:
"It is obvious that the completion of a cycle thus at no time has current moving other than in a single direction."

We have a "cycle" because the current alternates or reverses direction twice each cycle.

Hams likely agree with Terman that radio waves are produced to some extent whenever a wire in open space carries a high-frequency current. (Page 864, opus of 1955)

Kraus says on page 12 in the 3rd edition of "Antennas":
"Antennas convert electrons to photons, or vice versa."
Also: "Thus, time-changing current radiates and accelerated charge radiates."
Also: The currents on the transmission line flow out on the antenna and end there, but the fields associated with them keep on going.

Best regards, Richard Harrison, KB5WZI

Again, no technical statements coming from your mouth only taunts.
Just shows what sort of individual you are, always taking a poke at
people
with none having technical content. I am beginning to think of you as
a
small person in stature with a big chip on your shoulder and a
slobbering mouth.

Art:

Would be GREAT! And, much appreciated!

I am making a collection of books, I am sorting those with expired copyrights, and creating a "Tech Repository." I am working on this when bored and "in the mood." When it gets sorted into page(s) I am not ashamed of, will make it (page(s)) known ...

SEND AWAY MAN!

Warmest regards,
JS

Oh most celebrated Prior Art, sir of infinite wisdom,

You write about geography and vectors.

The compass uses magnetism where you have curled the North Pole into
Bermuda.

The complex conjugate coordinates of Bermuda locate Perth Australia.

You have place Amelia at the conjugate North Pole by your navigational
skills [sic].

It stands to reason that modest cab fare would have gotten her to town
to allow her to announce she wasn't lost.

Vectors prove this and Gauss' law was used!

OH! I get it. You don't understand the technical part of "other side
of the earth" and complex conjugate. You only have a degree in
Spanner Engineering, not English, so your affliction is noted.

> by answering a different one.

HP would be interested in knowing your theory that the
s-parameter equations cannot be used on a transmission
line. How can you possibly be that ignorant?

Actually, s-parameter equations are an ideal way to
analyze an impedance discontinuity in a transmission
line since the voltages are normalized to SQRT(Z0).
Squaring the normalized voltages yields power.

```
----50 ohm line--+--1/2WL 300 ohm line--50 ohm load
a1-->|-->b2
b1<--|<--a2
```

b1 = s11*a1 + s12*a2 b2 = s21*a1 + s22*a2

|a1|^2 is forward power, |b1|^2 is reflected power
|b2|^2 is forward power, |a2|^2 is reflected power

Squaring the s-parameter equations yields the power
density (irradiance) equation from the field of optics.
I'm sorry that technical fact upsets you so.

It's a swing and a miss. Strike three! You're out!

The entire point of s-parameter analysis is that the "network" can be
treated as a black box, characterized by the various parameters at the
ports. How does that work to analyze what is happening *inside* the box,
such as somewhere along the transmission line?

That's pretty simple to answer, Gene. Simply make
the black box infinitesimally thin so that events
are transparent. Ignorance is immediately alleviated.

267. meteor shower

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-03 21:09:04 UTC
From: Howard W3CQH <hsgorden@comcast.net>
Message-ID: <q9idnZrSJYIt0-DanZ2dnUVZ_qainZ2d@comcast.com>
Source record: 30083

Space Weather News for Jan. 3, 2008
http://spaceweather.com

METEOR SHOWER: Earth is about to pass through a stream of dusty debris from near-Earth asteroid 2003 EH1, producing the annual Quadrantid meteor shower. Forecasters expect a brief but intense peak of 50+ meteors per hour over Earth's northern hemisphere sometime between 0200 UTC and 0700 UTC on Friday morning, Jan. 4th. (Subtract 5 hours to convert UTC to EST.) The timing favors observers in the eastern USA, Europe and western parts of Asia. Winter storms frequently hide this shower from observers on the ground. To avoid such problems, a team of astronomers led by Peter Jenniskens of the SETI Institute plan to fly a plane above the clouds where they can train their cameras on the Quadrantids. Their data may reveal whether asteroid 2003 EH1 is the fragment of a broken-apart comet. Visit http://spaceweather.com for sky maps and more information.

JUST FOR FUN: This is a good time of year to see Orion the Hunter: the constellation rises in the east at sunset. Watching Orion ascend, you may experience the little-known "constellation illusion." The idea is the same as the Moon illusion; constellations viewed near the horizon look abnormally large. Go outside tonight and look. Can you believe your eyes?

> I don't understand the mechanism which causes waves to slosh.
> Would you mind posting the sloshing equation?

Cecil,

I am not Roy, but I will answer your question.

It is really *very* straightforward. As I hope you will agree, a standing wave is characterized by voltage and current that are in quadrature, both in time and in space. In other words, the current loops are spaced 1/4 wave from the voltage loops, and the current maximum occurs 1/4 cycle ahead of (or behind) the voltage maximum.

Let's look at conservation of energy, one of your favorite topics.

At some arbitrary starting time, the voltage loop is at a maximum, and the current is zero. At that time all of the energy in the standing wave is contained in the capacitive or E^2 term. The physical location of that energy is centered on the voltage loops.

As the cycle proceeds, the voltage decreases and the current increases. After 1/4 cycle the current is at a maximum and the voltage is zero. Now all of the energy in the standing wave is contained in the inductive or H^2 term. The physical location of that energy is centered on the current loops.

There are two important observations. First, the location of the standing wave energy has physically moved by 1/4 wave during the 1/4 cycle. That is the "sloshing" that some of us use as a description. Call it what you like.

The second observation is that the standing wave is not at all static. Energy is moving back and forth at the speed of light in the medium.

Some people like to treat standing waves as poor distant cousins to "real" waves, or perhaps only as "envelopes". It is their option to do so, but it misses the actual behavior of standing waves and "sloshing" energy.

The equations can be found in many places, such as Johnson's book on Transmission Lines and Networks.

When they collect these fragments are they like talcum powder that is
presently found on earth or are they moon dust like fragments. I
understand NASA have depleted their store of moon dust
which are jagged remnants of past collisions that storms have not
ground down. They need more moon dust to experiment on how to prevent
their entry into landing craft and the like.
Apparently one university is having success at growing crystals of
same.

Gene, I cannot find anywhere in the s-parameter information
where some of the network must be hidden inside a black box.
I always thought an s-parameter analysis could be done without
a black box. Could you help us out here and point out exactly
where it says a black box is a requirement. Seems to me the
purpose of an s-parameter analysis is to alleviate ignorance
which obviously doesn't match your agenda.

Cecil,

If your only concern is the definition of "sloshing", then about 100,000 messages have been wasted.

My definition of "sloshing" is as I stated. I believe that Roy would have the same definition. If your definition involves the speed of water, then I have no idea why that topic would be relevant here.

Not quite. The voltage following a pulse is zero; with my sine wave example the source continues producing a sine wave at all times while wave interaction is occurring.

> At the point of interaction, Keith's example has a reflection factor of
> 1 or zero, depending upon whether the waves bounce or pass. Keith's

Because there are no mathematics and, as far as I can see, no mechanism for wave interaction, I can't discuss Keith's example except from the standpoint that the waves don't interact. (Excluding, of course, superposition from the meaning of "interact".)

> In your example, the presence of voltage from the ideal source creates

Sorry, I don't accept the premise.

> By assuming that the waves reflect at the ideal source, you proved that
> the reflection factor is -1, which is the factor for a short circuit.

Yes, that is correct.

> This can not be the case, so waves must not reflect at the ideal voltage
> source, they must pass.

Well, yes it can be the case, and is. But let's see where rejection of this fact leads.

> vtot(t, 0) = vf(t, 0) + vr(t, 0)
>
> = sin(wt)tot = sin(wt) + sin(wt)
>
> = 2*sin(wt)
>
> Someone will certainly say the the vtot(t,0) at the source location is

I certainly say that.

> The conditions at
> point (t,0) itself is actually unknown (because vf mysteriously appears,
> and vr disappears by going off the transmission line), but point (t, >0)

> vtot(t, >0) = vf(t, >0) + vr(t, >0)
>
> = sin(wt)tot = sin(wt) + sin(wt)
>
> = 2*sin(wt)

So by rejecting the fact that the waves reflect at the ideal source, you're forced to conclude that the voltage at the output of a perfect source is unknown, with waves "mysteriously" appearing and disappearing. It also appears that you've violated Kirchoff's voltage law at the input. My analysis requires no such contradictions, unknown voltages, or mysteries. As an engineer, I like my analysis a whole lot better, because it can give me answers which are testably correct.

Can you use your theory to show the voltage at all times at the input or, if you choose, just inside the input of the line, as I've done using conventional theory?

I've used SPICE to verify my analysis. If I modify the SPICE model to show the voltage just inside the line, do you think it will show the voltage to be 2*sin(wt)? SPICE makes no assumptions about waves, bouncing or not, so if it shows sin(wt) (as it certainly will), where do you think its error is?

Why don't you try your favorite s-parameter reference, AN 95-1, page 6?

Since you are playing words games again by changing "can be treated"
into "requirement", I suppose you already are well aware of what AN 95-1
says.

Bermuda (or even the Bermuda triangle) are both 3000 to 4000 kM from
the equator. The "other side of the earth" doesn't even come close to
Howland Island OR the Pacific!

How much money would you put down? Better yet, would you fly with Art
as navigator with his level of accurate map reading?

No, it's the rate of energy delivery or movement, which is not quite the same thing.

> It always
> carries a time dimension having beginning and end. Power(watt)
> =v*i/(unit time) = 1 joule/second.

Sorry, you've got this wrong. One watt is indeed one joule/second, but P(t) = v(t) * i(t), period. Energy is the integral of P(t) dt. Power is the time derivative of energy, or dE(t)/dt where E is the energy.

You could as reasonably say that energy always "carries a time dimension". After all, one joule = 1 watt-second.

> In the example you give of charging a capacitor, the time dimension is
> lost, so you are correct that only energy is conserved. Power is lost.

Sorry, I don't understand that.

Ok, let's test this. Please tell me exactly how many watts are stored on the line of the second analysis (where the perfect source is in series with a 150 ohm resistor). Next, tell me how many watts will come out of the line if we quickly disconnect the perfect source and source resistance and replace it with:

A: A 50 ohm resistor, or
B: A 150 ohm resistor

> If power is stored, we implicitly store energy. Energy is v*i measured
> in joules without a time factor.

No, Energy is not v*i. Power is v*i. Energy is the time integral of v*i.
Power is not stored; energy is.

> Obviously we store energy on a
> transmission line when we store power.

I guess it would be obvious if you believe you can store power. But
before going further, please demonstrate what you mean by calculating
how many watts of power are stored on the example line. I showed exactly
how many joules of energy were stored, you can show how many watts of power.

> So if in the future, I use the term "power storage", please take it to
> mean that energy distributed over time is under consideration.

I'm afraid I'm not very good at translating what people mean when they
say something else. Why not call energy storage "energy storage", power
"power", and energy "energy"? Then I and hopefully other readers will
know what you mean. The MKSA unit of power is the watt, and of energy,
the joule. The two are no more the same than speed and distance, or
charge and current.

I hope
> the term might be useful to you as well.

No, I have enough trouble communicating when I take great care with my
terminology. The last thing I need is to be saying something which means
something else -- or means nothing at all. When I mean energy storage,
I'll say "energy storage", thank you.

I've used the term a few times in this forum, and in the context exactly as you explained, clearly, in your previous posting. And as I also have explained several times in this forum since I first used it to describe energy in a line with infinite SWR in a posting in December 2002. But you can fully expect to see the question asked again and again as it has been over the intervening five years. This is a good example of the reason I plonked Cecil some time ago.

I don't see Cecil's postings unless quoted by someone else, nor do I consider it anything but a waste of time and cause of pointless frustration to respond to him unless the answer would also potentially benefit other readers. So no one should interpret my lack of response to anything he directs to me as any sort of endorsement or agreement.

I tried to watch one of those meteor-showers a couple of years ago, but got a crick in my neck, then someone told me it may be easier if I would lay on my back in the bed of my pickup truck - so I tried that - to no avail. My wife said try it again without the camper-top - but what does she know about meteors?

Gad, with built-in failures of logic like this question, it is SO, SO
easy, I can do it in stereo:

First, I can pinch myself: corporeal reality! However, you are just
amusing words on a screen that I can erase at will, hence you are a
figment of the imagination - the essential seeminess.

Second (this is the same mystery investigated as the Chinese Room
Argument), your messages only appear to be intelligent. Subsequent
correspondence reveals that to be a fiction.

What a pair of slam dunks for the home team.

Want to go for the trifecta?

Both the first and second tests can be independently corroborated by a
multitude of other posters here!

Dubito Tu Es

Derek,
there are half a dozen more poles in our earth. Non ofcourse are as strong as the ferrite pole but none pass thru the geometric center of the earth so none can be exactly aligned on the opposite side of the center point. These poles being made of natural diamagnetic material
will have their lengths closest to the surface. All of course are weak but all are weighted by the inverse square law. and aligned at right angles to the ferrite pole (north and south)So at certain points on the surface of this earth all have a sweet spot for maximum impact on a small piece of ferrite metal shimmering tho balanced on a tiny pin when held in the hand.Don't take any notice of Richard he was a swabby for most of his time and never got the chance to look out the front of the ship.The bottom line is that he leaves nothing for you to ponder on so why converse with him? Os an aside Derek the majority of the earth's surface is covered by water which is diamagnetic. Both of the areas that I pointed to lie in a vaste area of water. I am not saying that compases malfunction in any way
but there are many aircrafts that have dissapeared in these areas without trace. Makes you think doesn't it.

I was born in London before the war. You can hardly make out the stars
because of the multitude of lights. This is the reasom of course that
the Greenwich observatory was abandoned. Had some visitors from London
a few years back and they spent all evening looking up at the clear
skies of illinois. Today it is much to cold for an old man to venture
out.

Howland Island is near dead on the Equator, Bermuda is not even close. Howland Island is near dead on the international date line, Bermuda is nowhere near the Prime Meridian (opposite side). The opposite side of the Earth for Howland Island would be south of the Ivory Coast in Central-West Africa!

I have sailed in the Bermuda triangle many times (to no shocking results) and Bermuda is three times closer to Boston than Quito Ecuador which is midway between the poles.

Bermuda is also on 65 degrees West longitude, 180 degrees away (or 115 degrees East longitude) is the Indian Ocean, not the Pacific (and I've been to both oceans too, crossing the full Pacific twice before I was 8 years old).

If nit picking amounts to a difference of 8000 kilometers, you must have your money on one hell of a spread.

This doesn't bode well for Art's magnetic compass correction factors. Even Gauss could tell the difference between the Indian Ocean and the Pacific Ocean (and he would have looked at a globe first before uttering this foolishness).

After all, this is really very simple stuff, but I guess you have to have been there to appreciate these nit picking issues.

As for diamagnetic curls of the magnetic field, if no one responded to this baloney, Art's ideas would die miserable solitary lives. Laughing at them is about the best currency exchange he can hope for.

No it doesn't. As soon as heat is dissipated, then we know that there is a real power component where current is in phase with voltage. I think in this case the insulating material broke down due to high voltage. The reason is that, with an unterminated coax, the reflected wave adds to the forward wave only at those portions of the line where the standing wave was at maximum and minimum. If the linear amp had a forward component at Vmax = 6KV, then the standing wave maximum and minimum would be +12KV and -12KV. Now, the minute the dielctric strength of the insulation material is exceeded, an arc is drawn inside the coax. This arc causes carbon to form and we have a carbon resistor path. This of course will occur only in the half WL sections corresponding to maxima and minima where the stress on the insulation is highest. It is not unusual for dielectric strengths to be exceeded. RG58U is rated at about 1.9KV which means that it will probably withstand 2X or about 4KV. I have no problem thinking that a coax like this would break down at the standing wave nodes and then continue to burn as energy continued to be dissipated in the damaged insulation from inner conductor to shield.

Your theory on the other hand, though possible, is lees likely in an amateur environment. The reason is that even a 22 AWG conductor can withstand a

rather large amount of current before it gets so hot as to melt and damage the thermoplastic insulation. Why is such a high current unlikely? Because in RF amateurs radio operators are dealing with high voltages and low currents in order to produce power. If this were an automotive circuit with a lead acid battery and high current, I think your scenario might be more likely (it is DC but you get the idea). Most amateur's do not deal with such high currents; we just don't have 50KW of power available to us like the commercial stations do.

> It relates to another bitter round in his own thread of trying to
> explain the confusion Hams have with Rhombic antennas and traveling
> waves to then discover standing waves line up and down them:

In any antenna, you will have a combination of standing waves and traveling waves. What I was saying was, in the above example, even if you started out with an open coax line and a perfect standing wave where no real power was dissipated, immediately after the insulation broke dow real power started dissipating and that component could only be composed of travelling waves, in phase with current and voltage.

Hi Dan,

That stands to reason.

>I think in this
>case the insulating material broke down due to high voltage.

However, that does not. You (and I) don't have enough information
(not that it matters in confounding Cecil).

>The reason is
>that, with an unterminated coax, the reflected wave adds to the forward wave
>only at those portions of the line where the standing wave was at maximum
>and minimum.

This is rote (aside from the rough and loose description).

> If the linear amp had a forward component at Vmax = 6KV, then
>the standing wave maximum and minimum would be +12KV and -12KV.
and this is the particular information neither of us has. How do you
know Jim was running a linear, much less resulting with that
particular voltage? The clipped voltage commentary is strictly
conjecture.

>Your theory on the other hand, though possible, is lees likely in an amateur
>environment. The reason is that even a 22 AWG conductor can withstand a
>rather large amount of current before it gets so hot as to melt and damage
>the thermoplastic insulation.

Fusing current for 22 AWG runs about 40A in ambient temperature. The
inner core is not in ambient, but rather it is insulated (as you well
testify), which lowers the current required to open it. We don't need

fusing current but it does establish a rather dramatic caloric upper limit that easily exceeds the capacity of plastic to sustain exposure to the obvious heat. It is enough to say that lower currents could easily melt the plastic without having to "blow the fuse" so-to-speak.

All that remains is additional information from Jim as to the physical clues of melting or carbonization. With thermal runaway a distinct probability, both probably occurred and it is then a chicken and egg problem. The wavelength distance of these burns from the open end will nail it down with far more assurance than anecdotal evidence.

It took me only one post to prove that with data. I am not responsible for Cecil's framing of the argument to the contrary. Most of Cecil's craft projects contain critical errors that collapse his argument into wandering statements. To this point of 400 postings, or so, absolutely no one has expressed any confusion that Cecil implied was his premise to explain in the original thread. His straw man kneed him in the groin before he could get in his first argument and the gasps of incredulity were his own. :-)

>What I was saying was, in the above example, even if you started out

It isn't that difficult, complex, or messy. All of this embroidery is like a traffic cop stopping you for speeding, and citing your violation in terms of galactic spin (tracking you at an even speed is vastly simpler and both you and the judge would be forced to agree that, yes, you were speeding).

Hi Richard,

One of the bug-a-boos of definition crafting is using the term within its own definition. Even worse, is to define in negative terms (there are an infinite number of things that so qualify) such as a suitcase is not a planet, not a speaker, not a window, not a.... ad nauseam.

In other words "Standing Waves" are not "Waves" is sloppy writing. Going on, "transporting momentum?" Egads! Now there's an example of over-the-top writing. It could only provoke a goggle-eyed question of "how is momentum transported?" FedEx or UPS?

Does transporting energy mean accelerating a moving charge? Or moving a static charge? Both are energy, and yet one usage is slightly more comprehensible than the other. Does a surfer violate this definition? Would he be classified under traveling waves? (groan)

Hecht may be a commendable spirit, but his acolytes are trashing his legacy.

I fail to see what Richard thinks he has proven except
that he disagrees with Balanis, Kraus, and Jasik. It
is obvious that a lot of people don't understand the
considerable difference between standing waves and
traveling waves on an antenna or on transmission lines.

Although every real-world antenna contains both standing
waves and traveling waves, a 1/2WL dipole is classified as
a standing-wave antenna and a terminated rhombic is
classified as a traveling-wave antenna. Anyone who is
interested can model those two antennas using EZNEC to
observe the considerable difference in the antenna
currents.

Balanis dedicates most of "Antenna Theory", Chapter 10,
Traveling Wave and Broadband Antennas", page 488, 2nd
edition, to traveling-wave antennas like the terminated
Beverage and rhombic.

Also from "Antennas" by Kraus & Marhefka, 3rd edition:
"The condition of a uniform traveling wave on an antenna
is one of considerable importance, as this condition may
be approximated in a number of antennas systems." He
talks about terminated Beverage and rhombic antennas as
examples of traveling-wave antennas.

Jasik says: "Practically all standing-wave long-wire
antennas have gone out of use with preference for the
traveling-wave types." He then discusses the terminated
rhombic as an example of a traveling-wave antenna.

J. C. Slater agrees with you. In "Microwave Transmission",
he wrote: "Particularly in coaxial lines, the limit to the
possible transmitted power is generally set by difficulties
of corona or sparking between the two conductors of the line.
The greatest practical reason for avoiding reflections is to
reduce the magnitude of these voltage maxima."

From The IEEE Dictionary:

"traveling-wave antenna - An antenna whose excitation
has a quasi-uniform progressive phase, as the result
of a single feeding wave traversing its length in
one direction only."

Here are some more quotes from The ARRL Antenna Book:
"All the antenna systems considered so far in this
chapter have been based on operation with standing
waves of current and voltage along the wire. ..."

It then describes the concept of a terminated antenna
and says: "In such an antenna there are no standing
waves, because all received power is absorbed at
either end." The terminated rhombic antenna is then
described.

About Beverage antennas: "Because the Beverage is a
traveling wave, terminated antenna, it has no standing
waves resulting from radio signals."

This is the discussion I was hoping Cecil would take up. I can assure you that the coax I was using was not lossless; RG58 is quite real in that respect. The source was probably good for a kilowatt at 2.4 GHz, though it's likely only a small fraction of that was actually coupled from the cavity by Langmuir probe into a 50 ohm termination of some sort. (This was 20 years ago, so some of the details have faded now.) The cable got hotter than a firecracker in a very short period of time over centimeter sized regions spaced some number of centimeters apart. The coax appeared to have melted due to excessive I^2R heating by the conductors. Skin effect apparently played no small role. I believe the voltage in question is not the voltage across the dielectric, but rather along the conductor. At my suggestion the experiment was not repeated. :-)

Well, that explains a Rhombic to clear up everyone's confusion! Gee,
Mr. Peabody, let's step into the "Way-Back machine" and find us an
example of this Beverage antenna!

I suppose this example would be either too real, and unrepresentative
of our Guru's pronouncements of RF purity;

OR

I suppose this example would be too text book, and unrepresentative of
our Guru's pronouncements of RF reality.

Gad, was is a loathsome degenerate like me suppose to do when faced
with a dilemma like this? I mean, damned if you do one, and damned if
you do the other.

The only choice is to use one of Cecil's designs and see what Cecil
would pop an aorta over.

So, with that in mind, I simply step into the Way-Back machine and
crank in Tue, 18 Dec 2007 09:33:23 -0600, Cecil Moore
<nospam@w5dxp.com> wrote:
>The traveling-wave file is:
>
>http://www.w5dxp.com/TravWave.EZ

It has already been demonstrated that it is inferior in design, but in
full faith to the original designer's intent of exhibiting a traveling
wave, I must stoop to accept less for the sake of embracing its
lineage (shudder).

Dear readers, we must take care not to upset the harmony of the
crystal spheres of our esteemed Guru of the Airwaves; however, fashion
dictates that the most recent withdrawal from the vaults above demand
an external radio signal, not one driving his divine inspiration. As
always, the best way to confound Cecil is to embrace his own work.
So, by the simple addition of ONE WIRE, 60 feet tall and located

100,000 feet away (we can't be bothered with interactions polluting this study) we then shift the source to this distant radio to see what currents are pressed upon the receiving antenna (as is such the obvious destiny of the Beverage).

SWR along the length of the line: 8:1

Hmm, must be the charm of the original designer that so pollutes those ancient tomes exposed to the cold cathode light of the Xerox. This shocking result is certainly not the product of original thinking.

At this juncture, dare I attempt something more conventional? After all, the Beverage is classically taller than Cecil's one foot tall munchkin. It also resides over real ground, which, after all, is the classic ingredient to its success. Having embraced damnation in using Cecil's I can't be burned in purgatory for any more normal design.

So, let's see what appears on the radio from designs that are more classic.

This time we have a 1000 meter long wire 3 meters above ground;
100,000 meters away is our transmitter;
we are operating on 3.8MHz;
the load of 600 Ohms is placed against a radial system below it;
there are 16 radials, each only 4 meters long, 1 centimeter above real, high accuracy ground.

We turn on the transmitter, and look at the SWR due to currents reported:
8:1 SWR at the transmitter end with the current phase swinging like a pendulum. With something like 300 segments, that is roughly a 18 degree shift per segment along the wire (Cecil's forecast was 0) over a continuum of 360 degrees (cycle repeats every 20 segments like clock work).

No doubt this unfortunate pair of designs (the prince and the pauper) will evoke calumny and rage against this miserable churl for presuming to interpret the mystic arts known only to the Gurus.

Another explanation might be that Traveling waves means something altogether different than how they are commonly discussed on this board. Perhaps the Xerox will reveal that nuance. Maybe it is a threshold issue. The Guru need only climb the mount for more tablets of scripture to render:
"All SWR less than 2:1 is henceforth decreed by holy writ
to be flat and conforming to the ecumenical standards of
Traveling Waves - so has it been said, so shall it ever be!"

The death of close friends and family members becomes increasingly common as you get older. However, the end of a loved one's life doesn't have to disable yours. Oftentimes, therapy can be of tremendous help in coping with loss and the feelings it can bring, such as pervasive sadness, isolation, hopelessness, or worthlessness.

Too often, a person's attitude is one of the biggest obstacles to getting help. Many people believe that they're too old to get help or that looking to therapy is a sign of weakness or moral failing. In fact, quite the opposite is true. Therapy is a treatment process that offers specialized techniques of caring that have been designed to provide support, insight, and guidance. You're never too old to benefit from the life-strengthening benefits of therapy.

Your therapist can provide help and support your efforts in some of the following important areas:

Expressing Your Grief

Expressing your sadness is the first step in accepting a loss. Therapy offers a confidential, comforting setting in which to express your feelings and the therapeutic relationship permits you to safely explore even your most deeply felt sources of loss.

Staying Connected

It's important to spend as much time as you can with friends and family and to continue going to places where people know you, like your place of worship or a social group in which you regularly participate. Your therapist can help guide and encourage your efforts to stay connected.

Pursuing Your Interests

Finding ways to continue enjoying life is not disrespectful to the memory of your loved one. If you find it's too difficult to enjoy an interest the two of you once shared, you and your therapist can together explore ideas for new activities you can make your own.

Throughout your lifetime, you have most likely been the person whom others have looked to for help in times of trouble. Know that it's okay for you to be at the receiving end of care and attention. You can turn to 4therapy's Therapist Locator for help in identifying a therapist in your area to help you as you cope with loss.

All good questions. But it appears that your underlying
suggestion is that charge and charge flow in the distributed
capacitance and inductance can not be used to analyze
transmission lines.

And yet I commonly see discussion of current in transmission
lines. Current is charge flow per unit time. Is this all
invalid? Must we abondon measurements of current? Voltage?
These are all based on the assumption of charge being
a useful concept.

Don't be so modest.

You have also claimed that for an amplifier which can
be modelled as a Thevenin or Norton equivalent circuit,
the output impedance can not be used to derive the
reflection coefficient.

You have claimed that the only way to prevent a
re-reflection at a generator is to use a circulator;
a 10 cent resistor will never do.

You have claimed that energy can cross a point on
the line where V or I is always 0.

You have claimed that there is great importance
to the terms "Traveling-Wave Current" and
"Standing-Wave Current" (the title of this thread).

And there were more that escape my memory.

I'd suggest that this is only if the concept of the
waves in question does not include energy. In the
limiting case of the two waves being identical no

energy crosses the nodes. In other cases, only a portion of the energy crosses the nodes.

If the concept of the waves includes energy, some explanation is required to account for the wave crossing the node, but its energy does not.

Some readers like to superpose energy just as they do voltage, but in general this is not a valid operation so I am uncomfortable using it as the explanation.

news:4a6616fb-0ae0-4416-bbfb-d85cce1a3522@t1g2000pra.googlegroups.com...

Sorry i have been absent for a while, been too busy with other work and had to turn this off to keep from spending all my time laughing at the postings. Are we going for another 1000 post thread? almost 2/3's of the way there now... here is a kick to keep it going.

>You have claimed that energy can cross a point on
>the line where V or I is always 0.

ah, so once you have a standing wave on a line then no energy can cross the voltage or current nodes?? thats interesting. so at the place where current is 'always' 0 the voltage is a max right? so what happens to the V^2/Z power at that point? is that not flowing past that point? conversely, at the point where voltage is always zero, what happens to the large I^2*R power at that point??? where does that go? then try this thought experiment... take a long coax with an open circuit end, feed it with sinusoidal ac so it has nice standing waves, keep it lossless just because that irritates some of the writers on here. then attach a pure resistance equal to Z0 at the open end. now, if energy can't pass the points where V or I is zero, and I is obviously zero at the open circuit at the end of the line there should be no power to flow into that resistor??? Oh, but wait, the voltage is a max there so the resistor could draw power from the voltage standing wave, but then what happens to the current standing wave? once the resistor drains the last half wave voltage wave how does energy get from the next standing wave into the far end one to replenish it if it can't flow across the voltage node?? sorry, i have to stop, about to start another laughing fit.

all of the above obvious contradictions become intuitively obvious once you completely forget the standing waves and think only in terms of the traveling waves. and remember, again just because it tweaks some correspondents on here, you only need the voltage OR the current traveling wave, either one is sufficient to completely describe the conditions on the line in either steady state or transient conditions. (as long as the line and components are all linear and time invarient, loss is not a problem for this statement to be true)

jimkelleyamps@gmail.com wrote:
> This is the discussion I was hoping Cecil would take up.

I did take it up. Power was dissipated in the process
of destroying the coax. There is zero real power in standing
waves. Therefore, standing waves did not destroy the
coax. By the process of elimination, it was traveling
waves that destroyed the coax. The failure of the coax
caused the system to shift into the transient state
thus changing the standing waves to traveling waves
which delivered the power to destroy the coax.

During the initial transient state, traveling wave
energy becomes standing wave energy that exists
through steady-state. During the final transient
state, that steady-state standing wave energy is
released back to traveling wave energy and dissipated
or radiated. During the failure of the coax, standing
wave energy becomes traveling wave energy once again
which delivered the power to destroy the coax.

J. C. Slater says it is more likely that the damage
occurred at the current nodes rather than at the
voltage nodes.

Sorry, Richard, that is a false statement. With traveling wave
antennas, there is a phase shift per segment. An antenna with
an SWR of 8:1 is neither a traveling-wave nor a standing-wave
antenna but is a hybrid between the two. As usual, you have
either confused yourself or are trying to confuse others.
Sometimes it is hard to tell which.

A 1/2WL dipole is a standing-wave antenna with an SWR ~20:1
on the antenna wire. Take a look at its current phase.

A traveling-wave antenna needs an SWR close to ~1:1 to be
a good example. Whether by accident or on purpose, yours
is a very poor example.

RF current is a *result* of the H-field in the EM
wave. There are photons involved making it different
from DC. Electrons may (or may not) "bounce" off of
each other but photons traveling in opposite directions
in a transmission line do not and cannot "bounce" off
of each other. They pass each other like ships in the
night. Any theory based on photons "bouncing" off of
each other while traveling in opposite directions, is
inaccurate and doomed to failure. Simply applying the
scientific method will remedy the problem.

which comes first, the current or the field? i contend that it is not necessary to consider the current or the h-field at all. use the voltage traveling wave and it is not necessary to consider current at all, hence where does the h-field come from? or consider the current traveling wave and then where does the e-field come from? forget photons when thinking of coax, antennas, currents, and waves, they will just confuse you.

And have proved it with concepts that existed before
I was born. I cannot take credit for that.

If an amplifier is delivering zero net power, the
calculated rho = SQRT(Pref/Pfor) = plus or minus 1.0
The value of the "output impedance" is irrelevant.
Because of superposition, the reflected energy never
encounters the "output impedance".

> You have claimed that the only way to prevent a
> re-reflection at a generator is to use a circulator;
> a 10 cent resistor will never do.

Roy has said essentially the same thing in so many
words. You see, your concepts lead to a direct
violation of the conservation of energy principle
for which I can take no credit.

> You have claimed that energy can cross a point on
> the line where V or I is always 0.

Since it is impossible for photons to reflect while
traveling in a homogeneous medium, that one is a
no-brainer. I cannot take credit for anything I
learned from Quantum Electrodynamics.

> You have claimed that there is great importance
> to the terms "Traveling-Wave Current" and
> "Standing-Wave Current" (the title of this thread).

Again, I didn't invent standing wave current and
traveling wave current. I am just reporting what
I have learned from people who knew the difference
before I was born. If one knows much of anything about
mathematics, one can look at the equation for standing
wave current and the equation for traveling wave current
and see the considerable differences. That you cannot
just proves that you don't know much of anything about
mathematics.

Standing wave current = Io*cos(kx)*cos(wt)

Traveling wave current = Io*cos(kx+wt)

I feel sorry for any "technical" person who cannot see the difference. For traveling waves, the position and phase are interlocked. For standing waves, the position and phase are divorced. Those differences are obvious and are plotted at.

This thread has become long, it is so long--everyone must have some sort of questions--or it (the thread) has prompted some sort of question(s) in their minds'. If not, so be it, I am a "weirdo" for it ...

1) Does a .0001 Hz signal use photons? A .001 Hz? A .01 Hz? A .1 Hz? A 1 Hz? I mean, at what "magical point" do photons become involved?

2) What experiment(s) have "seen" these photons? A fogging of film emulsion? ???

In all seriousness, I simply have a problem with photons doing much more than "vibrating in near-place." With light, I can imagine photons ...

Warm regards,
JS

Already answered. Any time electrons are accelerated or
decelerated, photons are involved. Any frequency of AC
can provide electron acceleration and deceleration.

> 2) What experiment(s) have "seen" these photons? A fogging of film
> emulsion? ???

Process of no-brainer elimination: Nothing else besides
photons can travel at the speed of light in a transmission
line (adjusted for the VF of the medium).

I used your Traveling Wave antenna. :-<

We can both agree the data reveals the truth of it being a very poor
example.

Dear Readers.

This was another slam-dunk. It was easier than collecting
unemployment. The simplest part is using Cecil's own examples and
drilling into their fault seams. Like this one, they usually split
open and spill their contents like an overripe watermelon.

It is unlikely that any better example will arrive that bears any
resemblance to what Beverage designed, so the data once again goes
undisputed in confounding the Guru of the Airwaves.

http://www.w5dxp.com/TravWave.EZ

Good grief, Richard! You cannot use the 8.4:1 50 ohm SWR
reading for the SWR on a wire with a characteristic
impedance of 411 ohms. I see what you did now and it
is was more than stupid.

The load resistor is 411 ohms. The characteristic impedance
of the wire is close to 411 ohms. Set the Alt SWR Z0 to
411 ohms and observe the actual SWR of 1.025:1.

The SWR is 1.025:1. The current on the wire is close to
100% traveling wave current. You observed the phase shift
and reported it. You have proved my point while trying
to discredit it. Thank you very much.

The reason that I didn't defend myself against what you
were saying is that I didn't believe anyone would be
so stupid as to report the 50 ohm SWR on a wire with
a characteristic impedance of 411 ohms. Therefore, I
didn't know you were talking about my example.

John
You are quite correct in requiring things to be relatively
simple . And RF is very simple when you do not try to make it
difficult.
A radiator in equilibrium is a full wave length and equates with
a mechanical pendulum which is about as close as you can get to
perpetual motion
Electrically it is seen as a parallel circuit sometimes called a tank
circuit.
It to like a pendulum passes the same energy backwards and forward and
losing just a bit to resistance losses.Ofcourse everybody knows that
the pendulum has also a circular motion as well as backwards and
forwards so if RF is to be compared to a pendulum we must be sure to
account for that rotative motion. Nothing so far is anything unusual.
Now we supply energy to the circuit or radiator. The initial current
enters the inductance and generates a magnetic field. The current
applied then reverses because it is AC or periodic DC.
Without support from flowing current the magnetic field starts to
collaps such that the energy
that it generates moves on the the capacitor which like the inductor

will stop the enrgy from getting by and thus stores it, It acts in a mirror image or opposite fashion to that of a conductor, when one discharges the other collects what is discharged. So far John it is all very simple since this can go on for ever backwards and forwards and if we lose a bit of energy along the way the current generator is there to replace what is lost.
Now we must look at the radiation properties as well as that circular movement that we saw with the pendulum which is the only thing left to describe.
In the atmosphere we have lots of dust that has penetrated the shields around earth. These are nothing fancy just dust particles. Actually these particles are called static particles and they just want to rest somewhere.The odd thing here that all metals will not allow it to settle
on them because like magnets with a hysterysis content they push away this galactic dust.
Fortunately there are some metals and matter that do not retain a internal hysterysis energy
pack like aluminum and copper and water so this duct pretty much seeks these out to settle on.
Nothing really difficults so far John, no fancy names or fancy bouncing.
So you see the reason why aluminum is used for radiators because they belong to a familly known as diamagnetic material. So what is so fancy about using aluminum to transport energy backwards and forward since aluminum is not specifically used for pendulums? well there is a specific reasons that the properties of aluminium fits in with current flow and RF generation.
First it has a skin that is difficult for current to penetrate so any field produced by current
can only be created outside the skin which unlike magnet material the field cannot penetrate the inner material. Fortunately it is conductive, on the othere side of the coin the field generated are weak because they do not have internal magnetic fields in the metal to support them. Still nothing special John , just a circuit sort of thing, no proton things or fancy names to muddy up the water. Noe let us look again as to what happens in the circuit.
Yup when the inductance creates a magnetic field it is a very weak field so the energy passed on to the cappacitor is very small. Never the less the acction of back and forth still goes on.
Now is when all the special things happen.
.....
The capacitor releases its energy like a blast of a opening door where the electrons stored with energy in their pockets blast their way towards the inductance. On the way it sweeps up
its brethberin electron particles that are devoid of energy on its way to the inductor.
The inductor is not interested in static or energy less electrons since the static does not have
any usefull energy required to make a mabnetic field .So the magnetic

field is generated on the outside of the inductance but here is the guts of radiation. Diagmatic materials when they produce a field produces a field at right angles to a normal ferromagnetic field. This field tho very weak parries the oncomming static particles away. The action spoken of for a momement disturbs the equilibrium that was in place such that the airborne static particles
are thrown away from the eaths gravitational field. Pretty neat John, nothing really new since all characteristics and properties are well known and documented.
Now reviewing what happenned and comparing it to a pendulum. Yup we had a back and forth motion but we already knew that because it was a tank circuit. The weak movement of the magnetic field created a 'curling' type action which paried the onrushing levitated particles away from the immediate scene. At the same time when all these levitated particals was forced upwards away from the radiator each particle provided an equal and opposite force which is applied to the radiator the impacts of which reflecting the changing energy flow from the capacitor. These multi impacts create a mechanical oscillation within the radiator.
See John, again nothing special, everything is known. It is just that like a jigsaw puzzle the complexity of which is determined from where one starts which in my case started with the Gaussian theory.The experts on the other hand did not know where to start so they inaiated new sciences
Oh, and another thing those particles that are now trying to escape the earth's gravity
field and in some cases bouncing off of the earths layers and comming back looking for a
radiater of the right material that it can arrive at to settle upon thus making a series of noises like a muscical box with a fantastic caphony of sound andc vivrations on a resonal antenna.
As I said before John,no fancy names or extra things moving around to take you attention away from what is really happening. All concurring phenomina is a matter of record by past very clever people which is beyond any doubt and, and I say 'and' like nature the mechanics of action are very, very simple.
Best Regards
Art Unwin.....KB9MZ...XG (uk)

Food for thought.

Consider an isolated transmission line charged to some DC voltage. Then initiate current by attaching a resistor. We can identify a wave moving back from the junction, beginning at the time of contact. We can also, by monitering the current or power through/into the resistor, plot a wave going through/into the resistor. The two waves would be mirror images of one another. The forward wave would clearly carry energy, the backmoving wave would be a "book keeping" wave that reported the energy removed from the transmission line.

The bookkeeping wave would really be the visible part/result of a power wave that is the negative equivalent of the wave passing through the resistor. Mathematically defining the energy component of the power wave, we should have If*Ef = 1 - Ib*Eb, where If and Ef are the instantaneous measured values of forward current and voltage, and Ib and Eb are the instantaneous measured values of bookkeeping current and voltage. The number 1 defines the beginning energy level as 1. We should observe that If = Ir. If so, then Ef = 1 - Er. Remember, these would be instantaneous values.

So it was, so it is, and so shall it always be to demonstrate a dramatic variation of CURRENT. All rather standard stuff. The SWR report from EZNEC is source based, and that source was 100km distant from the RECEIVE antenna - wholly remote from my care and consideration. I didn't make your mistake, you made it alone for yourself. Mount it like a trophy on your mantle with the rest.

With great misfortune, TravWave.EZ is, as you say, an atrocious antenna, and nothing like what Beverage designed which my second example more clearly reveals. I simply used your poor antenna so as to increase the likelihood of its impeachment by its designer. This, of course, triggered the script where that author condemned his own creation; and all the choreographed marks were hit precisely as anticipated.

Dear readers,

With such limp struggles as offered by Cecil, this has long passed the point of being a challenge. It rarely takes much effort to crack his arguments open, but having done it several times here alone, it can only be described as a Sado-Masochistic spectacle. My arm is getting tired with swinging the whip and Cecil's groans have long since lost their siren call. Perhaps some future outrage from Cecil will invigorate the song of the lash.

When dawn breaks, it will no doubt reveal TravWave.EZ disowned and cast out of the home as a fraud. I will undoubtedly be described as

its immoral progenitor because TravWave.EZ is so obviously the spawn of a demented troglodyte slipped into Cecil's nest like a cuckoo's egg.

Geez. What is the matter with you? Ofcource A.C reverses direction. I know you will fight change but in no way does that change anything other than we don't have a lot of things bouncing around like this long thread is suggesting as well as you .

>
> Hams likely agree with Terman that radio waves are produced to some
> extent whenever a wire in open space carries a high-frequency current.
> (Page 864, opus of 1955)

Ofcourse hams are aware that radio waves are produced when a wire is subject to a alternating current. They have normally call this wire a antenna or a radiator. Nothing special there either. What is your message OM?

>
> Kraus says on page 12 in the 3rd edition of "Antennas":
> "Antennas convert electrons to photons, or vice versa."

He could be correct in that opinion! there are many opinions out there including mine but other theories have not been established by previously known facts

> Also: "Thus, time-changing current radiates and accelerated charge
> radiates."

Richard, it is a basic fact that a time varying field creates radiation and I have explained in detail the sequence of events. I have NO problem with you debating a fact that I have given or even supply a equivalent sequal of events supplied by another that implicitly contradicts what I have written but you are just supplying words. Again what is your message?Spit it out please.

> Also: The currents on the transmission line flow out on the antenna and
> end there, but the fields associated with them keep on going.

No silly.

When the current stops decay begins. We have not found a means for perpetual energy
as far as I know. Current flow in a parallel circuit is maintained by a generator which re supplies energy that is lost in the circuit. When you turn off the generator the current flow stops. I really am not interested on what could happen when you turn the power off I just walk away and why not? I wish Richard you would stop putting spam on this thread
Surely there are other things for you to do in life other than dropping names and inane suggestions which by their very nature donot require a response. You are just copying the antics of the other Richards trying to taunt as if you are afraid of something which you want to put down. Why not find a truth and the use it to debate a position? That is called a debate or a conversation? There is no nead to bait and taunt.

The sentence is true, and is without need of the words 'real' and
'standing' to make it so.

> Therefore, standing waves did not destroy the
> coax.

:-) Yes and no. Were it not for waves standing on the coax, there
would have been no damage to the coax, and there wouldn't be an
explanation for the damage pattern. So your 'truism' has some
significant caveats. I guess that makes it more of a ....'half-truism'.

> By the process of elimination, it was traveling
> waves that destroyed the coax.

Kinda tough to have a standing wave in the absence of traveling waves
now, isn't it.

> During the initial transient state, traveling wave
> energy becomes standing wave energy that exists
> through steady-state.

So there's energy in the standing waves, but not power. Apparently
they're like traveling waves......that stand!

Probably best not to assume it's a 'different kind of wave' in the
first place. Maybe it would be better just to think of it as a
pattern formed by traveling waves - an appearance that traveling waves
can have under certain circumstances which produces stationary effects.

Yes I know that's basically what you've been trying to say "all
along", but you were saying it so poorly that it was indistinguishable
from fantasy.

> J. C. Slater says it is more likely that the damage

Source record: 29898

I haven't been following this particular discussion of "standing wave antennas" vs "traveling wave antennas" because it looks to me like just another diversion to avoid confronting the sticky problems with alternative theories, and one that's been used and discussed many times before. But I see that EZNEC's report of SWR has been mentioned, so I'd like to make sure that readers understand what it means.

EZNEC reports an "SWR" for each source, and will also plot this as a function of frequency. This is *not* the SWR on an antenna (assuming that you can even rigorously define it), nor is it necessarily the SWR on a transmission line to which the source is connected, if it is connected to a line. It's only an alternate way of describing the impedance seen by the source, just like your transmitter's SWR meter. The reported SWR is the the SWR which would exist on a 50 ohm transmission line if that transmission line were connected between the source and its load, whether one is or not. It shows the same value as your transmitter SWR meter would if you replaced the source with your transmitter. An alternate SWR Z0 value can be specified so you can also see what the SWR would be on a transmission line of some other impedance. It's not necessary, or even likely, that there will be a transmission line or even wire (again, if you can even define SWR for a single conductor) which actually has an SWR equal to the value reported by EZNEC.

If you were to connect your transmitter to a 50 ohm load through a half wavelength 300 ohm transmission line, the SWR on the transmission line would be 6:1, but your rig's SWR meter would read 1:1. If you modeled this with EZNEC, it would show the 50 ohm SWR as 1:1 (like your transmitter SWR meter). If you set the alternate SWR Z0 to 300 ohms, it would correctly show the 300 ohm SWR to be 6:1. If you connected your transmitter directly to a 150 ohm resistor, your rig's SWR meter (and EZNEC's 50 ohm SWR) would read 3:1, even though there is no transmission line of any impedance and therefore no standing waves anywhere.

Richard,

A few questions:

* Have you ever seen a surfer?
* Did you perhaps notice that the surfer typically travels much faster
than the water?
* Did you ever think that is why the boards are shaped the way they are?
* Did you ever wonder how the surfer moves around if he or she is only
riding on the moving water?
* Did you ever see one of those surfer parks where folks surf on
man-made waves that stay in one place?
* Do you think perhaps the slope of the water might be important?
* Does a traveling wave have a different slope than a standing wave?

What does Terman say about all of this?

That's your stupid mistake. The SWR on the wire is load-
based and is equal to 1.025:1, close enough to call that
wire a traveling-wave configuration. If you are so stupid
that you don't even recognize your stupid mistake, I don't
think anything can be done for you.

The load is 411 ohms. The Z0 of the wire is close to 411
ohms. The SWR on the wire is close to 1:1. It is a traveling
wave configuration essentially devoid of standing waves.
The traveling wave current pattern is obvious.

Hi Roy,

Cecil simply presumed (without reading the antenna specification, nor trusting his own design) that my report of SWR was based on a source exciting the line.

First, and evidence of his poor reading skills, I specified that I had constructed a remote transmitter antenna to excite the test antenna (there were two). As you offer in unquoted material, the SWR report would have related to that source, in its own environment. I was wholly unconcerned with that, specifically. All SWR determinations followed the rather more prosaic method of simply observing current magnitudes along the length of the line, much like my work at the bench when I made similar measurements with similar techniques traceable to NBS.

Second, and with attention to his own reference citation that a Beverage antenna "...has no standing waves resulting from radio signals;" I introduced this remote excitation to provide just that: "radio signals" and not transmit excitation. Obviously, Cecil spends more time Xeroxing authorities than reading them.

So, the net effect is I used his model, and his referenced authority, pulled them together into a simple test which shows that, yes, standing waves inhabit the length of HIS traveling wave antenna when it is excited externally (as it must to conform to his authority). As Cecil has condemned his own design, I then also repeated this exercise with a design that more faithfully follows Beverage's design principles.

Rather simple stuff.

Hi Keith,

I'd like to thank you for your thoughtful and courteous post.

I agree with your observation about superposition of energy [and
power]. In fact this would seem to lend support to the idea that
there can be no 'energy nodes' on a transmission line.

Question for you: can you reference a thermodynamic treatment of this
concept of 'energy not crossing a node'? I think that thermo should
relate to just about energy transfer issue we might want to discuss,
including electromagnetic energy.

Thanks,

Jim Kelley, AC6XG

It certainly has a bearing on whether standing wave current
can be used to determine the delay through a 75m loading coil
like you have said it can. Please take a look at the current
phase reported by EZNEC and tell us once again how an constant
phase at all points on the antenna at any particular time can
be used to measure delay through the wire.

>
> Can you use your theory to show the voltage at all times at the input
> or, if you choose, just inside the input of the line, as I've done using
> conventional theory?
Yes. Here is the difference. I am using a short cut by looking at the
way waves travel and superimpose. My assumption is that the input
impedance matches the impedance of the line. Thus 1v generates a 1v
sine wave. For a simple example, such as any multiple of 1/2 wave, this
causes current proportional to applied voltage and impedance of the
line. For example, 50v applied to a 50 ohm line gives a 1 amp current.

We know a line 1/2 wavelength long will absorb energy for the length of
time it takes for a wave to travel the length of line and return, so
power must be applied during the entire time. Obviously, 2 half waves
will be applied over that time period so the amount of energy on the
line is equal to the amount of energy contained in the power applied
over time by two half waves, so total power applied is 2 * initial power.

Equally obvious, by leaving the source connected after the reflected
wave has returned, the question of how the source reacts to the external
application of power must be answered. This is a second question,
unrelated to traveling waves on a transmission line. My answer to this
question is to disconnect the source and replace the source with a
connection identical to the condition at the far end of the transmission
line. You can see that this leaves the transmission line isolated with
power circulating on the line (is is POWER, time is involved).

Your solution (as presented in Analysis 2) and the Power Analysis was to keep the source supplied at all times in an attempt to create continuous real world conditions, as contrasted to my method of a quick and correctly timed disconnect. Both experiments are real world simulations and can be performed.

Your analysis is identical to what happens at a real world transmitter. A very good, automatically tuned transmitter! Your choice of an ideal voltage source amounts to setting conditions that automatically adjust for impedance changes as fast as the change happens. The transmission line sees an outgoing impedance change going from 150 ohms to infinity in your example. The source sees an outgoing impedance change from 200 ohms to infinity during the same analysis period.

It is interesting to compare the final voltage ratios (directly proportional to energy levels and directly proportional to power levels) on the transmission line to the SWR ratio. You used a SWR ratio of 3:1 and I used 1:1. You found that the total energy stored on the line was 4 times the initial energy applied, and I predicted that the total energy stored was 2 times the initial. The link here is that the power storage factor(SF) (I know you dislike the term) is found from

SF = SWR + 1.

Your storage factor was SF = 3 + 1 = 4. My storage factor was SF = 1 + 1 = 2.

If we can accept that the storage factor is always SF = SWR + 1 for all situations, then we have a very convient way to predict the voltage increase that results form impedance mismatch at a discontinuity. I am not yet ready to accept this generalization, but we should look at it more carefully.

Ending comment. Both your and my analysis are correct. Congratulations to both us!

The s-parameter equations do that automatically.
That's part of their usefulness.

Incidentally, the power reflection coefficients,
rho^2, and the power transmission coefficient,
(1-rho^2), also do the same thing. That's why
a power analysis is often easier than a voltage
analysis.

Good grief, Jim, please solve the following "identity".

cos(kx)*cos(wt) = cos(kx+wt)

Find all (x,t) for which that equation is true.
I'm expecting an "attitude adjustment" from you.
Everyone is invited to solve the above equation
for (x,t). Hint: I solved it a long time ago.

in my book
cos(a+b)=cos(a)cos(b)-sin(a)sin(b)
so cos(kx+wt) would expand to:
cos(kx)cos(wt)-sin(kx)sin(wt)
me thinks you are missing a few terms in your 'identity'.

That's a different analysis than I did. I did two, one in which the mismatch was infinite (perfect voltage source at the input) and one in which the voltage reflection coefficient at the source was 0.5. The case where the input is matched is simpler, because there is no re-reflection from the source.

Can your method be used to analyze a circuit which is mismatched at the source?

> line. For example, 50v applied to a 50 ohm line gives a 1 amp current.

It does for the time for one round trip. Then the current drops to zero if the line is matched at the source.

> We know a line 1/2 wavelength long will absorb energy for the length of
> time it takes for a wave to travel the length of line and return, so
> power must be applied during the entire time.

Yes.

> Obviously, 2 half waves
> will be applied over that time period so the amount of energy on the
> line is equal to the amount of energy contained in the power applied
> over time by two half waves, so total power applied is 2 * initial power.

You've lost me here. What's "total power"? Can you express it as an equation?

> Equally obvious, by leaving the source connected after the reflected
> wave has returned, the question of how the source reacts to the external
> application of power must be answered.

Well, the bit about "total power" wasn't obvious, so I'm not surprised
that what follows isn't either. You're apparently assuming that there
are waves of traveling power, which has led to demonstrably
self-contradictory results before, but let's see where it leads this time.

> This is a second question,
> unrelated to traveling waves on a transmission line. My answer to this
> question is to disconnect the source and replace the source with a
> connection identical to the condition at the far end of the transmission
> line.

Which I presume is the open circuited example.

> You can see that this leaves the transmission line isolated with
> power circulating on the line (is is POWER, time is involved).

The power at any point can easily be calculated, and it shows that
energy is moving back and forth on the line. There are no waves of power
moving about.

> Your solution (as presented in Analysis 2) and the Power Analysis was to
> keep the source supplied at all times in an attempt to create continuous
> real world conditions, as contrasted to my method of a quick and
> correctly timed disconnect. Both experiments are real world simulations
> and can be performed.

Ok. My method correctly predicts what will happen at any instant in
either case. Let's see how yours does.

> Your analysis is identical to what happens at a real world transmitter.
> A very good, automatically tuned transmitter!

I won't attempt to argue that, because of the great deal of controversy
about what the characteristics of a "real world transmitter" are. I make
no representation for my analysis other than what I stated: it uses an
ideal voltage source, which is rigorously defined and with
characteristics which are completely known, in conjunction with a
perfect resistance.

> Your choice of an ideal
> voltage source amounts to setting conditions that automatically adjust
> for impedance changes as fast as the change happens.

No, there is no change in impedance. The perfect source has a zero
impedance at all times. The resistance has an impedance equal to its
resistance at all times. The voltage of the voltage source stays
constant (that is, it puts out a sine wave of constant amplitude and
phase) at all times.

> The transmission
> line sees an outgoing impedance change going from 150 ohms to infinity
> in your example.

No, it sees a constant 150 ohms at all times.

> The source sees an outgoing impedance change from 200
> ohms to infinity during the same analysis period.

If you consider the analysis period to extend to steady state, then yes, that's correct. You might recall that the power into the line increased for one of the reflection periods because of the improved impedance match between the source and line (impedances of 150 and 250 ohms respectively) compared to the impedance match at other periods.

> It is interesting to compare the final voltage ratios (directly
> proportional to energy levels and directly proportional to power levels)
> on the transmission line to the SWR ratio.

The energy stored = 1/2 * C * v^2 + 1/2 * L * i^2, where v and i are the voltage and current at a very short section of line, and C and L are the capacitance and inductance, respectively, per that short section. As you can see, energy is not directly proportional to V by any means. There are places and times where energy is stored entirely in the magnetic field, and v is zero.

> You used a SWR ratio of 3:1
> and I used 1:1.

No, the SWR on the line was infinite in my example. It's determined entirely by the load impedance and the line's Z0. If you're assuming an open ended line, the SWR is infinite in your example also.

> You found that the total energy stored on the line was
> 4 times the initial energy applied,

No, the "initial energy" applied was zero. The analysis began with the assumption that the line was initially completely discharged. It sounds like you're confusing power, which had an initial value, and the energy, which accumulated over time.

and I predicted that the total
> energy stored was 2 times the initial.

Where and when did you predict that? What initial energy did you apply to the line? Can you do an analysis with the line initially discharged as I did?

> The link here is that the power
> storage factor(SF) (I know you dislike the term) is found from
>
> SF = SWR + 1.
>
> Your storage factor was SF = 3 + 1 = 4. My storage factor was
> SF = 1 + 1 = 2.

First of all, the SWR in my example was infinite, so by your calculation, the "power storage factor" was infinite.

> If we can accept that the storage factor is always SF = SWR + 1 for all
> situations, then we have a very convient way to predict the voltage

> increase that results form impedance mismatch at a discontinuity. I am
> not yet ready to accept this generalization, but we should look at it
> more carefully.

I still don't know what you mean by "power storage factor" or why you need to coin a new and vague term. So I guess I can accept that it's whatever you want it to be. But it has no relationship to power or energy that I can see.

> Ending comment. Both your and my analysis are correct. Congratulations
> to both us!

I've presented an analysis which gives, quantitatively, the exact voltage at any point on the line, at any instant, from turn-on until steady state. I've also shown the power being applied at any instant and the total energy on the line at any time.

You've presented an analysis whose only result is a poorly defined "power storage factor", derived from invalid premises.

Yes, congratulations to us both.

By the way, I didn't see from your "analysis" how many watts are stored in the line. If power is stored as you say, you surely must be able to determine how much.

356. Mounting 2 Meter ham antenna on Jeep CJ5 Softtop ?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-04 22:08:10 UTC
From: James <jnipperxxx@nospamfdn.com>

I plan to install a 2 meter radio in my 1980 CJ5 Jeep (softtop). My plan is to construct a mount that will attach to my rear tire mount. Because this will be a custom mount, I can have the base of the antenna even with the top of the spare tire, or I can elevate it some for greater height. I use this Jeep only in mountain areas. Here are some of my questions:

1. What is the "best" 2 meter antenna type for me (I don't need a dual bander. I will only use 2 meters). I know that a 5/8 whip will have the best gain, but I have seen some comments that a 1/4 wave may work better in the mountains, because of the angles involved. Yet, I know that a 1/4 wave needs a good ground plane, which a softop probably will not do very well. It would seem that with a 1/4 wave, I would want the base of the antenna at or near the top of the Jeep. I am also aware of a colinear antenna, but that would be quite tall for me !!

2. Is it best to have the antenna element fully above the top of the top of the Jeep ?

3. If I use a spring to offer some protection for the whip, doesn't the spring add to the length of the antenna, and I would have to tune the whip for resonance ?

4. What is the best (maybe strongest?) mount type ? I am accustomed to the 3/8" - 24 type stud mount. It seems strong to me. What are the advantages of the NMO and other mount types for my purpose ?

5. After choosing the antenna type (1/4 wave, 5/8 wave / etc) what is the best antenna ? Larsen, Diamond. Other ?

Thanks for any comments and advice, based on actual experience.

I'm sure your book is correct, Dave. Mine probably is too. (It has CRC Standard Mathematical Tables printed on the cover.) Cecil through a curve ball. The correct function for a standing wave can be written as the algebraic sum of two sine functions, or as the product of a sine and a cosine function e.g. y = 2*Ymax*sin(kx)cos(wt).

Hi Jim,

If that is asking for a manufacturer recommendation, I will leave that
to others.

>I know that a 5/8 whip will have
>the best gain, but I have seen some comments that a 1/4 wave may work better
>in the mountains, because of the angles involved.

Either works fine. Mountains are immaterial unless you are trying to
work off the pointy end of the vertical (even then, there is no
difference they both provide nulls). There is certainly a lower
directivity with higher angles, but higher angles also suggest closer
proximity. Any proximity that allows you to "see" the source would
also allow you to talk to the source. You don't need any
extraordinary amount of gain/power to accomplish that when a handheld
can talk to the space shuttle.

>Yet, I know that a 1/4
>wave needs a good ground plane, which a softop probably will not do very
>well.

So would a 5/8ths. You may be tempted with halfwaves (no ground plane
required). Take care, they can be wildly mistuned by nearby metal
and/or coax length, or any number of other considerations. This
follows the rule: no such thing as a free lunch.

> It would seem that with a 1/4 wave, I would want the base of the
>antenna at or near the top of the Jeep. I am also aware of a colinear
>antenna, but that would be quite tall for me !!

So stick with a single element. Gain is not all that it is cracked up
to be. Your intended mounting position will work just fine.

>2. Is it best to have the antenna element fully above the top of the top of
>the Jeep ?

If it were a hard top, then mounted dead center would be best. You
aren't likely to notice any difference anyway (and you don't have a
hard top).

>3. If I use a spring to offer some protection for the whip, doesn't the
>spring add to the length of the antenna, and I would have to tune the whip
>for resonance ?

Ya sure, you betcha. Buy a whip that is springy in its own right
(maybe using piano wire - this suggestion will probably attract flack,
just make it thicker wire).

>4. What is the best (maybe strongest?) mount type ? I am accustomed to
>the 3/8" - 24 type stud mount. It seems strong to me. What are the
>advantages of the NMO and other mount types for my purpose ?

All very fine. You can get by with less, but what is important is a
tight weather seal.

>5. After choosing the antenna type (1/4 wave, 5/8 wave / etc) what is
>the best antenna ? Larsen, Diamond. Other ?

All of the above.

I'm surprised that a physics professor doesn't recognize
the difference between the conventions of RF engineering
and optical physics (which are essentially meaningless).

Is discrediting me really worth denying the laws of physics?

Having been the owner of a CJ5 back in the 70's, I'd leave the soft-top alone, leaks bother me. Darn cover leaked air so bad it challenged the heater and won in cold/snow country--easily! Actually, wasn't that great even for California winters!

A pipe/tubing mounted to the bumper (are the bumpers still metal?) and one of the commercial 1/2 or 5/8 sounds good.

One of the helical wound fiberglass will get you going, remember, it won't be the last antenna you buy in life. Better yet, construct it yourself off some freely shared plans on the internet ...

Others recommendations may differ ... your choice. I'd just leave the soft-top alone ...

Regards,
JS

Based on mounting a lot of two-way radios in logging trucks in my younger years, I suggest mechanical strength is a prime consideration, and that if you are driving on unpaved roads the radiation pattern will vary anyway from bouncing around on the roads.

I suggest a Larsen 5/8 wave antenna in either NMO or 3/8 in hole mounts. Personally I prefer the NMO, but you need a 3/4 in hole saw unless you use one of the available "L" brackets. (Which come in both variants). I suggest the Larsen because it's tough. I know at least one logger who was still able to call for help from his overturned pickup with a Larsen on the roof.

As for ground plane, you can probably mount it to the spare wheel bracket or someplace similar. And while theory says you need to put it in the centre of a metal roof, you'll be able to communicate very effectively with all sorts of non-optimum placements. Make it mechanically secure, and out of the way of opening doors, hatches, windshields or hoods. Keep in mind the higher up you put it the more trouble you have with the whip hitting things overhead, like garage lightbulbs.

The other good thing is that the Larsens are easy to unscrew for going through the car wash after a muddy expedition! And the metal in the antenna whip is flexible enough you don't need an antenna spring that can come loose on rough roads.

There's no need to go to the weight and heft of a 3/8 24 mount - it's really designed for heavy (and huge) HF antennas. Either the 3/8 snap in or NMO mounts work fine for the smaller, lighter VHF antennas. The NMOs also are very low profile when the antenna itself is unscrewed, and both 1/4 wave and 5/8 wave antennas can be interchanged with the same style mount.

I have no connection with Larsen other than using them for the past twenty years and more, including all my vehicles.

> things fit into his equation??

David
you are quite correct in that I do fluctuate between a full wave
length and a half wave length antenna which is obviously wrong. My
problem in describing a wave length is to consider it in electric
terms thus a physical halfwave radiator is electrically a full wave
antenna since it handles one period. Ofcourse I should use standard
terminology and refer to physical length
even tho it is not exactly correct to my mind because it actually
varies in the real world where as electrical length doesn't. However,
I should stay with the accepted terminology to the best of my ability
even tho I believe that is why this arguement on colliding current is
realising postings and mass confusion in excess of 1000 each time it
comes up. I apologise for misleading terminolgy.
With reference to Gauss.
This is my starting point where with the addition of a time variable
to the static law became the same as Maxwells laws where Gauss formula
was firmly in theIsaac Newton camp
by revolving around gravitational fields.
Re: funny cosmic dust come into the equation
Cosmic or galactic dust is everywhere on this earth .m. This dust is
what Gauss refers to
as static particles in a gravitational field in equilibrium. Thus I
was able to add elements to this field as long as the elements were in
equilibrium, together with a time vaying addition which brings it into
Maxwells court. This transition to a dynamic form then allows the use
of computor programs based only around Maxwells laws. Thus radiators
and arrays could be designed based on a equilibrium format instead of
a planar format as with a Yagi using existing standard computor
radiator design programs. From the results the following becomes
correct i.e A radiator can be any shape, size or elevation as long it
is in aquilibrium
and made from a diamagnetic material. Thus now helix radiators would

have to have counter windings to fall with in these parameters, where the present helical antennas are absent the contra wound windings. All this is what Prof Hattely was looking for in combining the EH field which is unsuccesfull as is the latest RI antenna. None of these inventors followed the same trail that I did that revealed the equilibrium requirement for contra wound coil additions. Ask any other questions that you have difficulty with. As an aside, this was what Einstein was looking for during his last twenty years of life under the title of a Grand Unification theory but without success

Richard
You are just not reading what is written. The multi poles of the eath
do NOT dissect the center of the earth so their poles are never

exactly opposite but they are the other side of the World
Regarding diadmagnetic fields,
You have stated that to move a electron takes 10 to 100 x10 to the plus tenth value Tesla force which frankly is for a bonded electron or particle. A field to hold a inter galactic particle that Gauss calls static particles need only a magnetic field to the tune of 5 x 10 to the MINUS tenth value which is a very weak magnetic field and makes your figure look a bit silly. This compares favorability to a diagmagnetic field as formed from an aluminum conductor or radiator. This level of field can only marginally affect a ferrite based compass but I threw that in for general interest, especially when the field is generated at right angles to the normal ferrite magnetic field. I don't think anybody has determined why so many planes including a group of planes flew inexplicitely in the wrong direction in the Berbuda triangle where they perished or why Amelia failed to arrive at her destination after traversing several thousand miles succesfully on her journey around the world flight.But as far as the "foolishness" of a curving trajectory. It is well known that the earth turns. If you are not sure study a pendulum to see that it only not goes backwards and forwards but it also rotates, and there are many places that feature a large pendulum to illustrate this circular function.
If you are familier with vector forces you will note that one of the vectors is also called "curl" which mimics the weak diagmatic field of the earth but is magnified by a diamagnetic radiator based on the inverse square law.You also continually think or have a fixation in terms of a electron gun, which is a completely different animal compared to Galactic or interstellar dust that pervades this earth of ours. It sounds impressive but if you don't understand the nature of a static partical it does make you look silly with those knoweledgable in the field in the same way you decided to deride a Doctor from M.I.T. who is working on a NASA space project on a simple mathematical problem. So read carefully, and stop jumping to conclusions that are not intimated by my writings in efforts to anger people in your postings. I will not go as far as Cecil did by infering you are insane because I consider your comments are deliberate to precipitate anger, tho why you do this I do not know.

> Keith

~~~~~~
In order for the pulses to bounce off each other, your theory
requires that electrons move at nearly the speed of light.

Unfortunately, they do not. The classical formula for the drift
velocity of electrons in a conductor is:

v = I / (n * a * q)

where

v is the drift velocity of the electrons

I is the current in Amperes
~~~~~~

n is the number of electrons per cubic metre, copper = 8.5e28 / m^3

A is the cross sectional area of the wire

Q is the charge of an electron, 1.6e-19C

References:

http://amasci.com/miscon/speed.html

http://physicsplus.blogspot.com/2007/05/mcq-on-drift-velocity-of-electrons.html

http://resources.schoolscience.co.uk/CDA/16plus/copelech2pg3.html

http://hyperphysics.phy-astr.gsu.edu/HBASE/electric/ohmmic.html

Using the 1 Amp from your post, if the center conductor has an area
of 0.5 mm^2 (0.5e-6 m^2), the drift velocity is:

v = 1 / (8.5e28 * 0.5e-6 * 1.6e-19)

= 0.0001470 meters per second

So in one second, the electrons move 0.147 mm.

If the propagation constant of your line is 66%, the signal will
propagate at:

Vel = 3e8 * 0.66
= ~200e6 meters/sec

If the pulses meet in the center of the line, that point is about
400 million meters away from the electrons that originally carried
your pulse of charge.

This raises many questions. How can the pulses bounce off each other
if the electrons that carried the charge are 400 million meters
away? Obviously, they can't.

There's more bad news. If two collections of 1 Coulomb each were
concentrated one meter apart, the force between them could be
calculated from Coulomb's Law. In this example, the force is 1.01
million tons:

http://hyperphysics.phy-astr.gsu.edu/hbase/electric/elefor.html

This means the pulses could not even come close enough to bounce off
each other. This would certainly wreck any timing analysis you try
to do on the signals.

So your theory fails simple logic tests, it requires invalid
electron velocities, and it fails Coulomb's law.

It is clear the pulses cannot bounce off each other, as you claim
above when you state "But bounce it does."

~~~~~~
> But it appears that your underlying suggestion is that charge and
~~~~~~

> based on the assumption of charge being a useful concept.

You are just trying to fog the issue. You cannot use charge by
itself as you claim above.

> Keith

Probably a Lamda / 2 dipole, or a "sperrtopf"
(is there an English word?)
and then the base must be separated from chassis.

Yes, you have to add every thing behind the feed point.
Keep in mind that a spring is an extra instability of this antenna, and with
this length isn't necessary

In this case I would you recommend to use a 5/8 because the length would be
maybe reach near the top of an installed hardtop then a 1/4.

I suspect that this has nothing to do with the rf performance of the
antenna, and more to do with ground loops causing problems in the audio
stages of the car kit.

did this 'car kit' come with an antenna? did you use that antenna or the
one you already had?? i suspect that if they supplied you an antenna that
it was meant to be isolated from the vehicle ground, possibly it had its own
matching or decoupling system built in. by interrupting the braid you may
or may not be isolating that antenna from the body, some antennas include a
matching transformer in the base that connects to ground. it also seems
like they are worried about dc grounding and voltage differences, perhaps
they don't isolate the antenna connection in the phone very well from the
power, so i would be very careful about how it is connected and follow their
procedure and use their parts.

It might best be called a hypothesis, but I don't think
it requires that electrons move at the speed of light,
rather charge move at the speed of light.

This would seem consistent with normal explanations where
charge starts to enter the line at some time T and starts
to exit the line at T + distance/speedOfLight later.

[snipped, an interesting computation of the speed of
electros]

Another interesting analysis. It raises the question of how
a pulse containing one coulomb over a measurable length of
line actually maintains its shape and does not immediately
disperse.

This is a detail well beyond my knowledge, but I could
speculate that it is related to the inductance and
forces of the resulting magnetic field.

I'd further speculate that the force between the pulses
can not travel faster than the speed of light, and since
the pulse itself is travelling at the speed of light,
the two pulses reach each other at the same time that
force does.

Perhaps I was not clear in my post.

In any case, the question is fundamental...

Can charge and charge flow in the distributed capacitance and
inductance be used to analyze transmission lines?

> > Notice a key point about this description. It is completely in

No. I am just trying to make clear the consequences of choosing
"no" as the answer to the question I directly posed above.

...Keith

If you haven't committed to one design yet, you might look around for
or fabricate a tail light mount. Basically, the ones I;ve seen unbolt
the tail light, and are a stainless steel plate that has the same hole
patern as the bolts that secure the light. on top is a flap that is
bent forward drilled for the antenna mount. Advantages are, you don't
have to mess with it to change tires, it doesn't move to open the
tailgate (no extra coax to be stuffed somewhere), and if you put it on
the driver's side, it is very unlikely to be in you field of view on a
regular basis. As for sepcific antennas, I'd go for an inexpensive one
as long as reasonable.

Anything moving at the speed of light in a transmission
line is photonic in nature. The nature of photons is
well known and they do not repel each other. They have
electric and magnetic fields but no charge. So there's
no charge moving at the speed of light in a transmission
line.

For a softtop, no. For a (metal) hardtop yes. For a glass hardtop no.

If the spring is part of the antenna, yes. But only use a spring
designed for that particular antenna. Otherwise just make a spring
assembly for the entire mount instead.

yes. that is the classical derivation shown in any decent text book.

>> You are just trying to fog the issue. You cannot use charge by
>> itself as you claim above.

>No. I am just trying to make clear the consequences of choosing
>"no" as the answer to the question I directly posed above.

moving charge is current. current traveling waves are well defined and
analyzed by existing methods. as stated before and well documented in
existing texts you need only analyze the current OR the voltage traveling
waves in a transmission line to get the full picture since one is always
linearly related to the other by Z0. waves traveling in opposite directions
do not interact, they don't 'bounce' off of each other, they just pass right
through each other as long as the conditions required for superposition
apply, which is almost all the time in amateur installations.

Hi Stewart,

As Jeff points out, this is to accommodate the audio system and
whatever curious battery configurations your vehicles might present.

Moreover, it sounds like you bought the cheapest design on the market
(this doesn't mean you paid the lowest price, however) and their
instructions merely make up for their failure to invest in the best
design for the customer.

Your description of "interrupted the braid" could present a severe RF
performance penalty, making that cheapest design even cheaper, and
your loss more expensive.

DO NOT interrupt the braid. What the sense of this is to ISOLATE the
antenna's ground from the chassis. Magmount antennas do this quite
well, but then you have this wire snaking out to the mount which does

not give a very polished installation appearance (if you are going to consider that). Otherwise interrupt the chassis (punch a hole, or use an existing hole) and pass a half wave antenna through it, securing it in the best fashion possible (perhaps a glomp of rubber compound, or epoxy). You may be able to find insulated antenna mounts.

Nothing to do with the argument, but I believe there is an exception
that comes to exceeding the speed of light, and that is when the wave is
slowed in a medium to a speed less than c.

Hi Richard,

You are right, of course. Cecil's one-size-fits-all answers always fail abruptly.

What you are describing is associated with Cerenkov radiation (not the radiation, but the stimulus of the radiation, which is a charged particle traveling faster than the speed of light for the medium within which it travels).

Keith, if you could get people to subscribe to hyperphysics so that
they may
read of the tremendous strides with respect to radiation,it's speed,
acute
angles of radiation and the relationships to light and even to the
solar system, especially with respect to the Milky way. All of these
discussions with respect to collision of waves would disappear, since
all laws are based around equilibrium. When equilibrium is broken as
with a radiator that is not resonant one cannot procede as normal in
translating existing laws for a unbalanced situation. When one does
this one enters a circular debate that has no end like this one which
many suposedly experts have deviated from cardinal laws. If these so

called "experts" kept up with the modern phases of science as shown by hyperphysics which you have pointed to instead of remaining inthe stable position of their junior years learning by rote they would be constantly reminded of the importance of confining them selves to the world of equilibrium.
Alas, they prefer to live in the confines of the past where modern physisists prefer to keep pace with knoweledge. However, these new physists only communicate between themselves such there is a barrier between the old and the new, those who seek knoweledge and those that are content with the world of the past.
Regards
Art

oh yeah, art would like this one! if the braid is inside the spring, how
does it work? wouldn't the skin effect keep the current on the outside of
the spring? or is the braid for the current traveling back down the inside
of the antenna??? ART! Help!!!

Tsk, Tsk, Dave,

The spring is diamagnetic and bends itself towards your contact when
you transmit.

Sometimes EM waves travel at less than the speed of light
in a vacuum but they are still traveling at the speed
of light in the medium. VF*c is still the speed of light.

I agree. At 850MHz it is just as easy to make a 1/2 wave dipole as a 1/4 wave ground plane. The full legth of the dipole is only 18 cm. If that is what they're doing, then you want to stay as far away from ground as possible.

392. Re: Vehicle groundplane - theory question. Mobile phone-slightly OT.

Hi Stewart

You and I probably agree that there is no DC reason to *not* connect the antenna coax to ground. It should be easy to test to see if there is a DC voltage from the coax outer conductor to Ground. With zero voltage from the coax to ground, there is no reason to isolate the antenna end of the coax from ground. Thats easy to check with a voltmeter.

You and I probably also agree that there are lots of AC noise conducted
in the ground circuits of car bodies. Alternators are often very noisy
(400 Hz when alt is running about 3,450 RPM). Flashers can be noise
sources.If the antenna is grounded then noise can be introduced into the car
kit.
It seems that, if the only reason to *not* connect the coax to ground at
the monoploe base is " If the antenna is grounded then noise can be
introduced into the car
kit", the problem noise could be eliminated by including adequate conductor
from the roof to the input (12 volt negative's) DC terminal.

Jerry

When matching a very short whip one gets a big reading but
further down the road is could all be dissapeared.

Can a closeby fieldstrenght measurement be done ?
The magnetic field is also great with a short whip.

If you are changing nothing except the impedance matching, you can put
the field strength meter anywhere, and the highest reading will mean
you've adjusted it for the strongest signal at any distance.

Hello Norbert

A similar question appeared some days ago in a Dutch amateur radio newsgroup.

As Roy also mentioned, when you do not change the antenna (inclusive any ground system) and also not change the E-field meter position and orientation, but only change the matching, every dB increase in the near field, will give the same dB increase over distance. Assuming that your matching network does not produce significant E-field.

Determining the radiated power from near field measurements is theoretically possible, but not easy in real world for most amateurs.

You might measure the field strength at a certain (near field) distance. Run an EM simulation for your antenna construction (inclusive ground system if present). Compare the simulated (near field) E-field with the measured value. From the radiated power (in the simulation) you can calculate the radiated power from your antenna.

Best regards,

Wim

Sum Ting Wong;

The "Left" coast is how we refer to the US Pacific coast, specifically
California.

This designation is determined by looking to the north and extending
your left hand. This will now point to the left coast.

In Asia you would be pointing to the European Atlantic coast.

Just some American humor. HI HI.

Bob Casey is from Oradell, NJ which is on the Right Coast and I am
currently living in St. Louis, MO. What is your QTH?

Gentlemen
Radio is about fields , waves, inductors e.t.c and diamagnetic materials which does not include iron.!
So to refer to the magnetic field of iron has nothing to do with radio. For antennas we use diamagnetic materials which have a skin. None of these, when a current is passed thru them ,allows a field to be formed on the inside like a iron magnet ! So gentlemen, get back to basics and review what a field looks like under these circumstances. I am not going to tell you because your niche in life is to argue, so check things out for yourself. Think academicaly or in a scientific fashion instead of CB ers
And another thing. All laws are bound to the focal point of equilibrium. When there is not a state of equilibrium you have varying waves which do not appear when equilibrium is present.
So be specific if you are refering to a non equilibrium status since all laws must be modified to account for this. Otherwise, your debates will go on for years and years and years without closure

David
It certainly is not the same axis as the material that the current is
travelling through! Remember my comments with respect to a pendulum
when a eclipse occures, and the happennings in the Bermuda triangle!
If you did go to college look up your 101 notes or review the new
thread I have started for amateurs and socalled experts.
David, I am like an ever ready battery, I keep going and going until I
can educate all about how radiation occurs in a scientific fashion to
those who are not educated.
Unless debate points out errors that can be substantiated
I will go on and on and on and....

ok, lets make this simple. what is the equation for the vector
representation of the magnetic field around an infinitely long straight wire
made of copper? and what is the equation for it around a wire made of iron?
and how do they relate to the bermuda triangle? show all work, and complete
before the next eclipse.

"Educating" people using copious amounts of bafflegab has been
proven by Underwriters Laboratory to be a hazard to carbon life forms
of all types. You should cease and desist from this illogical behavior
says Dr. Spock. Captain Kirk seems to be in full agreement.
I asked Dr. McCoy about this, and he said, "Oh hell, it's too much
of that Vulcan Ale he's been drinking". Scotty had no comment,
but only scratched his head in disgust, and starting mumbling
something
about dilithium crystals never being in a true state of equilibrium,
even under the strict care and supervision of Dr. McCoy.
As a final comment, Captain Kirk said, well, there you have it then,
bafflgab is never in a true state of equilibrium. Even on the
Enterprise.
MK

Dr. Spock was a famous human pediatrician. Although perhaps not an expert on logic, he did write volumes about how to deal with children. So his advice is entirely appropriate in this situation, probably even more so than from the Mr. Spock of Star Trek.

Seems like the people on this side of the pond only got educated to
the level of their professors. So guys listen up.
When a current flows in a piece of iron it exhibites a field that is
representive of the north and south pole. Iron is referred to as a
ferrite matererial. When a current passes over a diamagnetic material
the field is representitive of a diamatic pole within the earth. This
pole is at a different angle to the ferrite pole and is also quite
weak. It is readily seen in action with a pendulum as it induces a
curve to its movement as it goes backwards and forwards. It moves more
erraticall when a eclipse occurs because tho the action tho weak is
enhanced the ferrite pole from out space is somewhat shielded and thus
magnifies the identification of the diamagnetic anti gravity forces.
This anti gravitational force can also create levitation, but is
really known as the offcenter force of our earth that turns the earth
around.
Now if you review the Corriolis effect or the Casmire effect you will
see that these are the effect created by poles other that that of
ferrite.
So now to a radio antenna. Surely you are aware that a capacitor
discharge moves towards a inductive field where at the same time it
sweeps up the static particles that have come to rest after entering
th atsmosphere (predominately during the active sunspot cycle.) When
the swarm or plasma cloud gets to the inductance it only accepts
charged electrons to make up a field. This field is a

antigravitational field that is oriented differently from a ferrite magnetic field. The field orientation thus guides what was the inate static particles into a curling action away from our antenna.This same action is in fact is called a curl vector when one determines the resultant vector of forces that emanate from a time varient field, which also is not parallel to the axis of the current flow.
Remember that this multi particle sweeping action occurs a million times for each megacycle of operation so there is a constant series of pulses or plasma stream moving away from the antenna. Each of these particles placed a reactive force upon the antenna such that with the abundance of
particles by virtue of the numourous samples supplied creates an occillating action on the radiator. This same sample of forces travels with the plasm until it finds a diamagnetic material that is resonant where it can impart the same occillatory movement on its new resting place. What is special about the resting place chosen is that only a dimagnetic material will allow these static particles to rest upon their surface, because all other materials have retained magnetic properties as seen when looking at a hysteresis curve.

Now with respect to Amelia Erhardt and the Bermuda triangle. What I was ponting to was that the axis of the diagmatic pole could well lie on this very axis where the dimagnetic field would be quite a bit stronger than elsewhere.
Put into place that both of these areas is surrounded by water which is also diamagnetic. Think then of a aeroplane made of aluminum enclosure that exihibits a shielding action as with a eclipse. Could not one wonder what could happen to a small ferrite sliver used in a compass when reacting to such circumstances especially when considering the universal square law? Would a few degrees of movement on a compass create a situation where a resulting course change would be made? I know this really has nothing to do with radiation but well.....you did ask.
Don't take my word for all this . Investigate via Google on all the phenomina spoken of. Use a computor program with an optimiser and determine why the radiator is tipped away from being parallel to earth.
Did equilibrium create an array where the radiators were closer to each other than a yagi? Check out where the gain difference comes from when radiators are stacked but with only one feed point. I could go on ofcourse,but I do recognise that old hams resist change so acceptance of the above is doomed. Cover the undeniable facts and kick Art from the group!
Can't do that I keep going and going and....

He doesn't have to be tweaked. He seems to grab at every straw
that is within reach.
Oh, and it's not like I hang around just to tweak Art..
And I'm surely no expert at electromagnetic theory
compared to many here.
But on the other hand, I don't spew out bafflegab on a weekly
basis either though, and then try to claim said "theory" as fact.
And that I am an expert, and everyone else is surely brain dead
if they don't except said bafflegab as gospel.
Art does this though. This is why it's hard to resist tweaking
him every once in a while. :/

He may well be on to some new exotic theory to set all mankind
on it's tail, but if he can't describe it without using bafflegab,
no one will ever be able to tell what he is talking about.
Myself, I'm not holding my breath... I don't believe in free
lunches.

Aet wrote:
"WHY? beCAUSE THE MAGNETIC FIELD LINES FROM A DIAMAGNETIC MATERIAL SUCH AS ALUMINUM OR COPPER IS AT RIGHT ANGLES TO THE AXIS OF CURRENT FLOW WHICH IS NOT THE SAME AS WITH A FERRITE MAGNETIC MATERIAL.

My experience with broadcast towers is that it matters not if a steel tower is painted or zinc coated it works the same.

Terman`s 1955 opus says on page 21:
"When a current is flowing through such a conductor (he makes no distinction between iron or copper, but does describe an isolated round wire), the magnetic flux that results is in the form of concentric circles, as shown in Fig. 2-9. It is to be noted that some of the flux exists within the conductor and therefore links with , i.e.,encircles, current near the center of the conductor while not linking with current flowing near the surface. The result is that the inductance of the central part of the conductor is greater than the inductance of the part of the conductor near the surface; this is because of the greater number of flux linkages existing in the central region."

Terman is describing "skin effect".

"Right hand rule" definitions also say magnetic flux encircles the current carrying conductor. Art`s assertion is "off the wall".

Probably so. But pseudo experts such as Roy and Tom and the three
Richards can't put o neck hold on the advances of science for ever,
for people like MK to follow in lockstep in the absence of knoweledge.
As for you Dave you can never move forward while resisting the notion

that the addition of a time varient field to Gaussian law of Statics
becomes the same as Maxwell's law. Without understanding the
relationships of laws with the state of equilibrium you will never
exceed beyond the learning level of your professor, only their equal.
Because of learning by rote without understanding of the first
principles of science all of which revolve around the lynch pin of
equilibrium. But you are not alone. All of the so called experts on
this newsgroup are guilty of the same thing
hanging on to the writings of Terman and other oldies while ignoring
or resisting the movement of science during the last half century.
But then today,s interests of hams is talking and handwaving and not
the intricacies of modern science with respect to radiation.

Hi Dan,

I don't know about ions; but, sure, voltage standing wave measurement
is as accurate as current standing wave measurement. Or perhaps you
need to make your question a little more terse (don't rely on the
continuity of discussion involving Cecil's quotes to fully inform any
argument).

In other words, filter out the static and frame your own question.

Typical of the three Richards, no content on antennas because his
degree was in English thus is lost with physics and old history like
Terman
and his experience is a sailor scrubbing the decks. Enjoy an evening
with your male masculane males or what ever they are called until you
can stand no more and fall asleep in their arms

Permanent magnets are collections of current loops, so it is supposed thet the earth`s magnetism is caused by currents in the earth. Its poles approach alignment with the earth`s axis of rotation.

Solar storms are seen to affect the earth`s magnetism and evidence exists that poles have reversed over the eons of history. The most recent reversal came about 2.5 million years ago.

"College Physics" by Frank Miller, Jr. is the source of the above.

No. It is keeping up to date. Terman died before all these things
become known and basically you are also dead when you cannot move
forward with the times. Go to google and look up diamagnetic materials
and diamagnetic fields. While you are at it check out the rotation of
a pendulum and how its curls are explained. While you are at it
explain why a radiator being parallel to the earth does not produce as
much horizontal gain as a tipped antenna.I dare you to come back and
explain what you discovered.
You can't hold back father time or the advance of science by holding
on to old books. Methinks you are better staying with ficticious waves
that bounce into each other with the other instant experts.

sure, VSWR is just as valid as Current-SWR, they are absolutely identical...
the only difference is that VSWR is the amateur 'standard' because it was
frequently easier to measure the voltage than the current... i.e. on open
wire feeders all you had to do was run a neon bulb or other cheap voltmeter
along the line to find the min and max voltage points... for a current
measurement you would have to couple a loop around the line or insert
shunts, not nearly as simple as measuring a voltage... so vswr was the
'standard'... though just plain swr, refering to either one, is just as
proper.
```

Does it matter that aluminum and copper are paramagnetic rather than diamagnetic? Perhaps you should consider a bismuth antenna. That is the poster child for diamagnetic metals.

But Tom,
this newsgroup is for auguments. Nobody is responding to the science
of antennas. Nobody has the knoweledge to refute statements supplied
How about just you and I discuss radiation and how it is created?
That sort of thing may interest people other than the instant experts.
For instance, I would love a counter discussion to what I have
theorised

even if it shows me to be in error, but this requires more than handwaving . I know you are knoweledgable about the things I have discussed where as others are still back in the old days and thus cannot contribute on a modern basis..
If we make a "field" all will follow and leave the puffed up pretend experts in the dust. At least the thread would NOT consist mainly of one person which would be a change.On top of that they would read a civil discussion that has not happened in a long while.
As for Dave he has not had what is known as a education,Witness his denials of static versus dynamic fields, where I know of no written text book that alignes with him. You just can't fake an engineering structured education.
Best regards
Art

Your TNT vest appears to be quite tightly laced up. Cutting off
circulation is it? I don't think many here are interested your side
topic choice of underwear.

Seems like a pattern in educated discussion is converging on the
reality that there isn't much educated topic here in the first place -
and that is how we got into this waltz.

Is your dance card empty?

Yes, bismuth would be the ideal material. On the other hand my
understanding is aluminum, copper,water, gold and the like are
diamagnetic materials. I am basing that on the magnetic susceptability
values and the like to make that distinction.Where are you drawing the
line with respect to diamagnetic and paramagnetic? The idea of using a
ingredient that could smother an already weak paramagnetic field seams
to thwart the actions that I am refering to.

But you said (in CAPS), "8:1 as evidenced by CURRENT on the wire. :-), You cannot make a SWR measurement on a receive antenna any other way." Sorry if the CAPS made my response look terse but I was only repeating your word verbatim.

Given that, just as with the voltage VSWR, the current standing wave is merely a depiction of the envelope of maximum amd minimum current values at the various points along distance kx, how do you measure the standing wave current on the wire? Do you use a current loop and measure the maxima and minima of a great number of points on a line and then plot the ISWR outer envelope on graph paper? My point is that standing wave current does not travel through the wire, it merely oscillates at different max/min amplitudes on each of the infinite number of points on the line. It cannot be measured directly with a current loop.

The VSWR meter on the ham rig is merely looking at the balance of forward and reflected "power" and it is calibrated to read it out as VSWR (or SWR). It may as well say "ISWR"; it is all the same thing. But it is not measured by sensing either voltage ot current going into the antenna...it measures the delta power.

Hello Art, the concept of SWR is extremely misunderstood even by people with degrees in electronics engineering. It is assumed to be simple, yet many people get it wrong. Indeed, a good understanding is essential for antenna development. I do not fault anyone for not understanding the concept because standing waves, simple as they may seem, are actually expressed as the product of a cos wave over distance and a sine wave over time. Many things are happening over the length of the antenna as the function is operating. If you think of it, it is the essence of space-time and it may be productive for you to consider it even more broadly in your own hypotheses, more broadly that is by possibly incorporating the mechancial SWR analogues to voltage/current SWR's and who knows what new ideas may come to mind with your model.

Exactly right. Power in the near field is largely reactive. To determine radiated power you measure the in-phase volt-amperes with a wattmeter. The multimeter on the hood maximizes output same as a Bird wattmeter for practical results, but you hanen`t quantified watts out.

Yes it was ok. Ofcourse Tesla like Vincent and Prof Hately and Hart
ignored the king pin of equilibrium thinking resonance and equilibrium
could be equated as the same.
When Tesla started to pump energy into the earth to prove the method
of transferring energy there was a huge explosion in the hinta land of
Russia which westerners were not allowed to view. Thus this was taken
as evidence that energy could be passed thru the ground. What created
the explosion in Russia
is unknown even to this day.(the FBI stole all Teslas records and
destroyed them as they considered Tesla a possible enemy, to the
dismay of science.
The antenna with a capacitive top is just a way to modify
a non resonant antenna by enlarging the capacitive content of the
radiator. That immediately violated the root(LC) ratio required for
Maxwells law thus it is then the "system" that was made resonant
instead of the radiator alone.
John.What interested you most?
Best regards
Art

Hi Dan,

All very true, but the meaning to you is what you are questioning I am
quite sure, and as I am quite comfortable with what I meant (I wrote
it after all), just what is your question?

>Given that, just as with the voltage VSWR, the current standing wave is
>merely a depiction of the envelope of maximum amd minimum current values at
>the various points along distance kx, how do you measure the standing wave
>current on the wire?

It is reported with every other aspect of the antenna by EZNEC. You
should acquaint yourself with the common reports provided by it or
other modelers in the NEC field.

>Do you use a current loop and measure the maxima and
>minima of a great number of points on a line and then plot the ISWR outer
>envelope on graph paper? My point is that standing wave current does not
>travel through the wire, it merely oscillates at different max/min
>amplitudes on each of the infinite number of points on the line. It cannot
>be measured directly with a current loop.

Traveling? You've got yourself twisted around the axle. I've
measured these phenomenon professionally, to NBS standards across the
full range of RF out to 12GHz. Although the technique can be heavily
invested with up-front work, and certain methods must be chosen with
care, conceptually it is quite simple.

>The VSWR meter on the ham rig is merely looking at the balance of forward
>and reflected "power" and it is calibrated to read it out as VSWR (or SWR).
>It may as well say "ISWR"; it is all the same thing. But it is not measured
>by sensing either voltage ot current going into the antenna...it measures
>the delta power.

99% of correspondents here have never had any experience with
determining SWR beyond the meter you just described. SWR was being
measured long before its invention, and you would be hard pressed to
find one in a laboratory (except as a customer's item to be tested).

Now, if you would simply take my advice to heart: strip away the static and ask the question that is plaguing you.

TravWave.EZ is not really an antenna. It is a loaded 1/4WL single-
wire transmission line designed to display the nature of
traveling waves. Take a look at the current phase vs the current
phase of StndWave.EZ. Both files are available from my web page.

It is more an artificial ground toaster. It bears no more
relationship to an antenna than its applicability to
Standing/Traveling Waves does to the Prince of Orange.

Source record: 29861

I've made a program to help visualize some transmission line phenomena. With it, you can see the voltage, current, power, and energy on a transmission line. This is a prototype of a work in progress. I've spent more time than I should on it already, but will add some features and increase its flexibility as time permits.

The program, named TLVis1.exe, is available from http://eznec.com/misc/rraa/. It doesn't require any installation and should run on most machines. If it complains about missing files, an easy way to make sure you have the correct run time files is to download and install the free EZNEC demo program from http://eznec.com.

Here's how to use it:

First, notice the scroll bar at the lower right. It allows you to select among five different demonstration setups. This selection bar is disabled while graphs are being run or displayed. Clicking Run will start the selected demo or, if paused, will resume it. You can pause the analysis at any time, step time forward or backward one step at a time with the appropriate button, and resume with the Run button.

For all demos, the transmission line is lossless, open circuited at the end, and 3 wavelengths long. The display shows various quantities (voltage, current, power, or energy) as a function of position along the line -- the source end is to the left and the load end to the right. The display at different times shows the quantity along the line at diffent times. Please keep in mind that the horizontal axis is position along the line, not time.

For demos 1 - 4, the input consists of a perfect voltage source and series resistance. The resistance value is three times the Z0 of the transmission line, resulting in a purely real input reflection cofficient of +0.5.

For demo 5, only, there is no series resistance at the input, so the input reflection coefficient is -1.0.

DEMO 1

Demo 1 shows the combined forward and combined reverse traveling voltage and current waves, and the total voltage. Start the program and click Run. You'll see black sinusoidal waves moving to the right. These are the initial voltage and current waves. They show as black because the forward wave is also the total until the wave reaches the far end of the line.

Pause the display when the reflected waves are about half way back to the source. Notice that the forward V and I waves (green) are always in phase, and the reverse V and I waves (red) are always out of phase. Also note that at any point along the line, the total is the sum of the forward and reverse waves.

Resume the analysis by clicking Run. As additional waves accumulate, all the forward waves are combined to be shown as a single forward wave (green) and the reverse waves are likewise combined (red). Watch the voltage and current at the input and output ends of the line. At the output end, the current is zero at all times, and the voltage is at a maximum there. At the input end, there's initially some current, as shown by the black line going up and down at the very input of the line. There's a time-varying voltage at the input at all times, although it changes in value as various reflections take place. As the analysis runs, the system slowly approaches steady state. Eventually, you'll see that the current at the input end has dropped to zero, as it must, since there can be no power at the line input at steady state because the output end is open circuited.

Pause the display once steady state is reached and step the time forward or back a few steps. Notice that there are times when the voltage is zero everywhere along the line, and other times when the current is zero everywhere along the line. This is true only when the SWR is infinite, as it is here.

DEMO 2

Clear the display and click the end of the slider bar to select demo #2. The lower graph shows the energy per unit distance on the line. This is an energy density, since it's per unit distance, and the total energy on any span of line is the integral of the energy density over that span. But I'll refer to the density as "energy" for simplicity. The energy is separated into two components, Ee and Eh. Ee is the energy stored in the line's capacitance as an E field. Eh is the energy stored in the line's inductance as an H field. The total energy is the sum of these. The upper graph shows the total V and I at the same time.

During the initial forward transit, you see only a green line for the voltage and current. This is because they're normalized to the same peak value (I = V/Z0), so they exactly coincide. The V line is drawn last, so it's all you see during this time. Unlike V and I, Ee and Eh have the same units and so are drawn to scale. Ee is exactly the same as Eh during the initial forward wave (that is, exactly half the energy at every point along the line is stored in the E field and half as an H field), so all you see is the Ee trace, and the total which is exactly twice as much.

When the reflected wave returns, though, the energy is no longer stored evenly between E and H, but swaps between one and the other. This gets pretty interesting as steady state is approached. Steady state is reached, for practical purposes, when the I trace at the input remains zero at all times. Pause the display when you reach that point, and use

the single step buttons to watch the energy in slow motion. Several things are notable:

-- There is no place on the line where the energy is always zero. It's zero momentarily only at particular places only.
-- There are moments when the energy density is the same at all places along the line.
-- The relationship between Ee and Eh is the same everywhere on the line at any given time. In other words, the energy swaps between Ee and Eh everywhere on the line at the same time. So there are times when all the
energy everywhere on the is stored in the E field and times where it's all stored in the H field.

The energy seems to form an initial forward wave, then reflect and re-reflect to form a standing wave. See the comments in the demo 3 description about this.

A word of caution, though -- some or all these wouldn't be true if there was a finite load rather than an open cicruit at the far end of the line.

DEMO 3

Clear the display and select demo 3.

The top graph is the same as for demo 2, but the bottom graph shows the power at each point along the line. The power tells us the magnitude and direction of energy flow -- when the power is positive, energy is flowing to the right at that point; when negative, to the left; and when zero there is no energy moving past that point. The amount of energy being moved is proportional to the magnitude of the power. The power at any point is the product of V and I at that point; V and I are shown in the upper graph.

Click Run and notice that there seems to be a power "wave" moving to the right, although its period is half the period of V or I. And it exhibits a standing wave just like V or I, except the frequency with which it oscillates up and down is twice that of V or I. The power is zero everywhere on the line at those times when either the voltage or current is zero everywhere.

It's important to note that this power distribution, which can seemingly be described as a sum of forward and reverse traveling waves, isn't made up of a forward wave made from the forward voltage and current waves and a reverse wave from the reverse voltage and current waves. It's calculated from the total voltage and current, not separate forward and reverse waves. Nor do the power "waves" represent average power. It's instantaneous power whose average value over any integral number of V or I half cycles is zero, and whose average over any half wavelength of line is zero.

DEMO 4

Clear the display and select demo 4.

This shows power and energy density at the same time, with power as the top graph and energy as the lower.

Pause the display when the analysis has reached steady state, indicated by the power at the input end of the line remaining at zero at all times. Single step until the total energy trace is as flat as you can get it, meaning that an equal amount of energy is stored in each small part of the line. The power waveform is at its maximum amplitude at this time, meaning that energy is moving as rapidly as it ever does. Look at the first power peak, just to the right of the line input (left side of graph). At that point along the line, the energy is moving to the right at its maximum rate. Click the "Single Step >" button once. You can see that the energy just to the right of that maximum-power point has increased, and to the left it's decreased. (It decreased to the left even though the power waveform is positive because more energy was required from the line just to its right than it was being furnished from the left.) Look carefully as you step and you'll see that the power graph isn't the derivative of the energy graph (although it looks that way at some times). That's because these are graphs of position, not time, and power is the *time*, not position, derivative of energy.

Single step until you reach the time when the power is zero everywhere along the line. The energy distribution is the most uneven at that time. Click one step forward or back and notice that the energy graph changes very little -- zero power means there's no movement of energy at that time.

DEMO 5

This is the same setup as demo 1 except that the source resistor has been replaced by a short circuit, leaving a perfect voltage source connected directly to the input end of the line and an input reflection coefficient of -1. An analysis I did and posted showed the input voltage oscillating among three values, one of which was zero, and never reaching a stable steady state. This display shows that behavior.

It's been interesting to develop and work with this program. I hope you'll learn from it as I have. I'll post notices as I make improvements to it.

446. Antenna designs for noise cancellation on HF bands

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-07 11:09:36 UTC
From: cliff wright <c.c.wright@paradise.net.nz>
Message-ID: <4782085f$1@clear.net.nz>
Source record: 29862

Hi! Any one come across any designs for recieving antennas for HF
(especially 14 MHz) for use in a situation with a lot of QRN.
This seems to be radiated from local power lines, but despite the lnes
in our subdivision being underground we still get a S6/S7 noise level.
Yes we have contacted the authorities but so far no useful result.
It seems somewhat worse on my 5/8 wave vertical than on my G5RV doublet.
Neither myself no a neighbouring Ham have been able to find a way around
this problem despite us both being experienced "old timers".
Some sort of "noise antenna" and phasing arrangement is contemplated but
we have not as yet found a suitable design.
Any ideas welcome!

Genius educated in Geee land and "correcting" the "dummies" misconceptions, but doesn't know the difference between the director - reflector, polarity - polarization, ferrite - ferrous, etc. When trying to make some sense of his "writings" and incoherent blabbing, you get the picture of troll with an attitude.

Hi Richard,

You can determine radiated power and radiation pattern by near field measurements (theoretically). Please search for "poynting theorem" and "Huygens principle", "Huygens Source" or "Fresnel diffraction theory". Most texts require differential vector calculus.

Because determining radiated power based on E- and H-Field measurement is generally not feasible for amateurs (and even for many professionals), I suggested another approach based on E-field measurements and EM simulation.

As absolute E-field measurement and EM simulation are within the reach of amateur radio operators, one can both tune for maximum field and determine absolute radiated power.

Of course you don't know how much power is dissipated in nearby structures (buildings, etc).

Best regards,

Wim

Your motive with all this handing waving is unclear.
It's only purpose is to illustrate traveling waves on a
single piece of wire. You can make the wire 1/4WL or any
other length. And the same thing can be illustrated by a
model of a terminated rhombic antenna in free space.

http://www.w5dxp.com/rhombicT.EZ

This is a terminated rhombic in free space. The termination
resistor is 880 ohms and the 880 ohm feedpoint SWR is 1.032:1.
Take a look at the current with and without the phase. Then
compare that traveling-wave current to the standing-wave current
on a 1/2WL dipole. Or simply learn enough math to tell the
difference between Io*cos(kx)*cos(wt) and Io*cos(kx+wt).

One really should take a look at the math before waving one's
hands and opening one's mouth in ignorance.

Please enlighten us as to exactly what trig "identity" will make
the following terms equal.

E1*e^j(wt-kx) ?=? E2*e^j(wt-kx) + E2*e^j(wt+kx)

Seems to me the only condition for which they are equal is when
E2=0, i.e. when reflections (and therefore standing waves) don't
exist.

Three pieces of wire, one of them yours (a piece of trash as you
describe it; and two of mine, following the conventions of their
designers). The demonstration is remarkable enough to accomplish what
you set out to do, clear up the confusion about standing waves on a
Rhombic, and then later a Beverage

Thanks, Roy. It is very interesting.

I'm having a hard time getting my head around Demo 5. The waves go away periodically (every 8 wavelengths?), sort of like a squegging oscillator. (By the way, it appears that the line is two wavelengths long rather than three.) This was totally unexpected. I will think more about this and try to picture the reason.

Nice tool.

John

Which, of course, has nothing to do with Standing Waves ON THE
ANTENNA.

On wire 1, the variation that is swinging along the line like any
other Standing Wave antenna of length greater than a quarter wave. The
value is higher than your "source SWR," of course.

>Take a look at the current with and without the phase.

Swinging 180 degrees at 6 or 7 degrees per segment. Exactly like my
earlier reports in contrast to your proclamations.

> Then
>compare that traveling-wave current to the standing-wave current
>on a 1/2WL dipole. Or simply learn enough math to tell the
>difference between Io*cos(kx)*cos(wt) and Io*cos(kx+wt).

I was there weeks ago ahead of you where the formula applies (on the
wire, not an EZNEC report of source SWR).

It was more interesting to compare your Rhombic to itself in a closer
to ground situation (elevated 12 feet above a real, high accuracy
ground).

SWR there, out of the gate (not at the source) and on the antenna wire
itself (where traveling waves would be presumed to inhabit the
design):
SWR: 1.15
Further down the wires, radiation loss does ameliorate this
SWR: 1.08
Still in excess of your Source SWR, which, obviously has nothing to do
with STANDING/TRAVELING WAVES ON THE WIRE.

Nice of you to confirm every point I made in refuting your claims.

Others are free to observe every classic indication of Standing Waves
upon a "Traveling Wave" antenna, complete with phase shift as I had
reported some time ago.

Some might not realize, Tesla and Einstein were friends, they were given opportunities to "pick each others brains."

The turbine he designed/built is still used today in virtually unaltered design ... his tesla coils virtually "cover the net" and it is difficult to conduct a through search on antennas/theory and not to start running into such ... a truly amazing man for his time--I wonder if he would not even stand as such if born in our time. But thank goodness he wasn't--he put us "ahead of the game."

Regards,
JS

Wim, PA3DJS wrote:
"Of course you don`t know how much power is dissipated in nearby structures (buildings, etc)."

Yes. Standard broadcast field strengths are measured at distances along radial paths begining at one mile from the station to ensure far field determination. Conductivity of the earth affects received signal strength. Over sea water, the millivolts per meter decline inversely with distance. Over the earth, decline is more rapid depending on conductivity. Some sites along the radials are unacceptable due to proximity of conducting structures. The more measurements along a radial, the better. 25 sites per radial is about the minimum. In the USA, the FCC has published Groundwave Field vs Distance Charts, and made them a part of its rules. One can try to fit his measured data to the FCC curves. Groundwaves is what broadcasting is all about at these frequencies.

Best regards, Richard Harrison, KB5WZI

Hi Folks,

This is my first post to this group. I'm a EE, so I've
had all the theory - now I want to know how these things
work. :)

Basically, my question is this: how can a a TV antanna
cover, what, 60 MHz to 800 MHz? That's over three octaves,
and if the antenna elements are designed to be a fixed
portion of a wavelength, why does this work over such a
large range?

It's because all of it is the driven element.

What you are thinking about is a Yagi antenna. A Yagi has
only one driven element a refelctor at the rear, and
directors in front of it. The more directors you add,
the narrower the beam width (how wide a signal
it transmits or the direction it receives from).
As you narrow the beam width the gain increases,
for each halving of the beam width, the gain doubles.

Eventually you reach a point of diminishing returns
which seems to be around 12db.

A log periodic antenna, such as a TV antenna consists of
many driven elements of varying sizes. I don't know if
it is necessary, or just works better, but they are fed
out of phase, i.e. the connection to the next element
(really a dipole) is reversed.

The easiest way to tell a Yagi from a log periodic is
that a yagi antenna the elements except the driven one
is a single piece and they are not insulated from the boom.

A log periodic antenna is made up of a set of dipoles, so
each one is split in the middle and insulated. Often you
can see the feed wires criss-crossed.

Note that log periodic antennas are not used everywhere for
TV signals. In the U.S. tv stations tend to be clustered around
large cities and often the same area. A log periodic makes sense
because you point it in the general direction of the TV stations.

Here it is quite different, there are only 2 TV channels over the air,
while at one time there were four. They were all in different directions

and different bands, 1 VHF to the east, one to the far north, and 2 UHF stations near the coast. So a log periodic made no sense and you see lots of yagi antennas.

I was talking the other night to a friend who lives in the U.S. and he is not sure what he is going to do. Although all the transmitters in his city are close to each other and about 8 miles from his house in the same direction, he can't receive HD TV reliably with them.

When analog TV is stopped, he'll probably have to go to cable or DBS.

Geoff.

There's no confusion. Terminated rhombics and Beverages are
traveling-wave antennas. Their currents are primarily:

I(x,t) = Io*cos(kx-wt)

A 1/2WL dipole is a standing-wave antenna. It's current is
primarily:

I(x,t) = Io*cos(kx)*cos(wt)

There's no confusion except in your mind.

The more elements it has, the better it works. So a cheap one doesn't work very well due to few elements. But there are ways to spread the bandwidth of elements by making a radiator out of V-shaped pieces of metal or tubes or wires in a V configuration - - the thicker the elements, the wider the bandwidth. Also configurations related to the log periodic array widen the bandwidth. A UHF antenna in the form of a single circular loop evidently has a wide bandwidth.

The SWR on the antenna has nothing to do with the standing
waves on the antenna?????? Good grief, Richard, it makes
sense now. You don't even know what a standing-wave antenna
is - so allow me to explain.

An antenna has a characteristic impedance range. If the
terminating resistor is in the center of that range,
reflections are reduced to a negligible value. That's
why terminated antennas are (usually) classified as
traveling-wave antennas - because they minimize reflections.

The ends of a dipole are (surprise) an open-circuit. All
of the forward wave is reflected. That's why a dipole is
a *standing-wave antenna*. There is nothing except radiation
that can reduce the reflections.

Sorry, nothing else you could have to say would make any
difference with a gross misconception like that.

By convention, x=0 and t=0 are at the feedpoint with the same
phase as the feedpoint signal. Thus, at the feedpoint, the
current is equal, but at no other point until one wavelength
is reached.

You'll find a detailed analysis which derives the reason for the behavior in my posting on Dec. 28 in this thread. You can see it by going to http://tinyurl.com/ypfshd. I agree it's counter-intuitive. It's a consequence of the contrived zero-loss system.

Hi Randy

You have probably thought about Log Periodic Antennas. They work by
forcing a null in the direction away from their feed point. The "dipoles"
that most nearly match the line connecting them will be the most active of
all. The active dipoles will be near 1/2 wave long. Each succeeding
dipole is fed 180 degrees from the dipoles on either side.
When the frequency is trippled, the dipole patern changes such that the
lobes add in a way favorable to the desired pattern if the dipoles are bent
to make the Log Periodic Vee Antenna.
There is a 3 to 1 relation inherant in the LPV that coincides with the
near 3 to 1 spread in assigned TV channels.

Jerry KD6JDJ

For those who haven't followed the discussion (which I fully understand), you'll find a mathematical analysis of the system of demos 1-4 in my postings of Jan. 1 in this thread. The voltage distribution development from startup is in http://tinyurl.com/27uzrf, and an analysis of the power at the input and the energy entering the system was in a second posting also on Jan. 1; you can find it at http://tinyurl.com/ypo2b4. The system of demo 5 which has the unusual response was analyzed in my posting of Dec. 28, http://tinyurl.com/ypfshd. The first and third include links to SPICE output plots which illustrate the time responses. (Note that they don't look like the TLVis1 plots because the SPICE plots have time as the horizontal axis while TLVis1 has position along the line as the horizontal axis.)

The analyses, SPICE results, and TLVis1 outputs should all agree.

Cecil, Can you help me understand that the end of a dipole is an open
circuit?
Nothing falls out because the current changes direction ala AC because
the end of a dipole equates with the time that requires the current
changes direction. So where is the open circuit? I also cannot see why
radiation reduces reflection if the circuit can be completed with
iron!
Best regards

I highly recommend that you get a couple of basic antenna texts. Very few people understand how antennas work, but they're nonetheless free with advice and explanations. Texts are generally reliable. The _ARRL Antenna Book_ is about the only book I can recommend that covers the topic at less than an engineering level. For engineering texts, Kraus' _Antennas_ is the gold standard. You can find earlier editions at very reasonable prices. There are, of course, a number of other very good texts. Be very careful of information you get from the Internet, including newsgroups.

As a person who develops, sells, and uses antenna modeling software, I also highly recommend this as an educational tool. I guarantee you'll learn a lot about antennas by doing some modeling. The free demo version of EZNEC is available at http://eznec.com, but there are other free programs available.

> large range?

One answer to your question is that "work" isn't a binary quantity but a continuum. TV antennas typically work considerably better at some frequencies than others. They just have to work well enough to provide an adequate signal to the receiver, and hopefully provide some directionality to reduce multipath interference. Most are a sort of combination of Yagi and log-periodic designs, with a lot of tweaking and trickery. Another respondent mentioned that elements are sometimes bent into a V shape. This little trick provides an element which has a bidirectional pattern at two frequencies related by a factor of three -- about the ratio of the high VHF to low VHF channels. Elements naturally are resonant at multiple frequencies, including frequencies related by a factor of three.

Good luck with your endeavors!

Demo 5 is a demonstration of the pitfalls of dealing with discontinuities. The demonstration portrays equal periods of sequential open circuit conditions and short circuit conditions.

The discontinuity here is that a reflection factor of 1 is used if the returning voltage is less than the initial voltage, but a reflection factor of -1 is used for any returning voltage exceeding the initial voltage.

Demo 5 is a demonstration of why a Thevenin voltage source is much to be prefered over a simple ideal voltage source for continuous running circuits.

Another way of illustrating the problem is to say that the ideal voltage source overwhelms any voltage from a returning wave. If an external voltage less than the initial voltage is applied to the ideal voltage source, vr = 0, vf = videal. If the external voltage exceeds the initial voltage, then vr = 0, vf = 0 This is a discontinuity, which shows up in Demo 5.

A third way of illustrating the discontinuity problem is to say that you can not apply a voltage to two wires that are short circuited at the input. In Demo 5, the reflected wave returns to find the circuit short circuited. On the other hand, the ideal voltage source applied voltage to an open circuit. We can not have it both ways.

Roy's work is only provided as an example of the use of mathematical notation.

The notation "vf1(t, x)" is not fully explained in the text, so any reader who is unfamiliar with the notation must do some additional study. This describes my situation, so after some study, this is what I think these terms mean, focusing on the two coordinates, wt and x.

Roy is using phasor math here, a subject comprehensively covered elsewhere. (Link http://campus.murraystate.edu/tsm/tsm118/Ch6/ch6_5/ch6_5.htm) The sum of "wt" and "x" denote the phase angle of the wave, measured in degrees, both referenced to zero. Two angles are needed, one to represent the physical location of each wave as a function of time, the second to locate the point of examination of the wave. "wt" locates the wave in time and physical space . "x" locates the examination point in physical space (on a transmission line in this case).

How is "x" located on the transmission line?

My automatic assumption was that "x" was based at the input to the line. Thus, if the input was on the left side of the page, the line would extend to the right, and x would become larger when moving right. This led to a contradiction when I considered how the wave reflects from the right side upon encountering a discontinuity. Suddenly, a positive reflected wave represented by sine(-x) was made sine(x) at an open circuit. At position sin(90), the wave reversed and became sine(-90). It was if a factor of -1 was applied to the analysis, which was not the case here.

After considerable thought and time, I realized that the origin of "x" was not at the input point, but was at the reflection point. Then the notation made perfect sense.

Forward wave->
input->_____|Reflection point
++x <- increasing x <- Reflected wave 0

Scale both the sine wave and physical line in degrees. The wave will repeat every 360 degrees (2pi radians). The x scale can be as long (in degrees or radians) as desired

Think of the sine wave as an curve traced on a MOVING sheet of paper. The paper/curve moves in the direction of the forward wave. As the sine wave trace passes the zero point, the wave has a(unit) magnitude, described as sin(wt). Pick any wt and match wt to 0 on the physical scale. Then go to the x location of interest to find the magnitude of the sine wave at that location for one instant of time (wt).

If a reflected wave is present, think of the same wave picture but moving in the opposite direction. When the reflection point is an open circuit, the reflected wave is generated by the forward wave so the two waves will always have a 1 to 1 corespondence at the zero point (point of reflection). The two waves are related by

For the forward wave, vf(t, x) = sin(wt - x)
For the reflected wave, vr(t, x) = sin(wt + x)

For the total voltage at any point (open circuit case).
vtot = vf(t, x) + vr(t, x)
= sin(wt - x) + sin(wt + x)

When the reflection point is a short circuit, the voltage becomes zero at the short. The sum of forward and reflected wave voltages (at the short) will always be zero. Mathematically, this is accomplished by multiplying either the forward or reflective part of the equation a factor of -1. The effect is to shift the phase of both forward and reflected waves by 90 degrees for a total of 180 degrees. We will apply the factor of -1 to the forward wave to maintain polarity consistancy with the open circuit case.

vfS(t, x) = -sine(wt - x) For short circuit reflection.

Notice that if x = 0,

vtotS(t, x) = -vfS(t, x) + vrS(t, x)
= -sine(wt) + sine(wt)
= 0

For practice, let's analyze a transmission line fed at one end, open at the other. The relfections will have a voltage equal to the forward voltage at all times so we will use the equation
vtot = sin(wt - x) + sin(wt + x)

Assuming one volt peak for the sine wave amplitude (a unit amplitude), find the voltage at points vtot(wt, x),(0,0),(90,0),(180,0),(270,0),(360,0). Notice that every voltage will be computed at the reflection point, x = 0.

For 0,0, vtot(wt,x) = sine(0 - 0) + sine(0 + 0) = 0
For 90,0 vtot(wt,x) = sine(90 - 0) + sine(90 + 0) = 2v
For 180,0, vtot(wt,x) = sine(180 - 0) + sine(180 + 0) = 0
For 270,0, vtot(wt,x) = sine(270 - 0) + sine(270 + 0) = -2v
For 360,0, vtot(wt,x) = sine(360 - 0) + sine(360 + 0) = 0

In this example, one complete sine wave cycle has passed the x origin.

For the next example, let's assume we want to compute the voltage at the point located 45 degrees from the reflection point at the same time that the voltage at the end is at a maximum. The maximum points for voltage at the end occurs when the 90 and 270 degree phases reach the reflection point. Lets look at the 90 degree case.

For 90,45, vtot(wt,x) = sine(90 - 45) + sine(90 + 45)
= sine(45) + sine(135)
= 0.707 + 0.707
= 1.414v
For 90,135, vtot(wt,x) = sine(90 - 135) + sine(90 + 135) = 0
= sine(-45) + sine(225)
= sine(225) + sine(225)
= -0.707 + (-0.707)
= -1.414v

We can continue this process to find the voltage envelope for any location/phase relationship desired. It works equally well for the short circuit case.

Let's look at the case for short circuited 0 degree case, where the phase is 0 degrees, and examination point is 90 degrees.

For 0,90 (short circuit),
vtotS(wt,x) = - sine(0 - 90) + sine(0 + 90)

= - sine(-90) + sine(90)
= - sine(270) + sine(90)
= -(-1) + 1
= 2

Now advance the phase at 45 degrees, and examine x = 90 degrees

For 45,90 (short circuit)
vtotS(wt,x) = - sine(45 - 90) + sine(45 + 90)
= - sine(-45) + sine(135)
= - sine(315) + sine(135)
= -(-0.707) + (0.707)
= 1.414

Now advance the phase to 90 degrees, examine at x = 90 degrees.
For 90,90, (short circuit),
vtotS(wr,x)= - sine(90 - 90) + sine(90 + 90)
= - sine(0) + sine(180)
= - 0 + 0
= 0

This discussion focused on voltage. Similar notation is used in equations for current and power.

That's not correct. A voltage source reflection factor of -1 is always used for the perfect source case, both in my analysis and in the program. See my analysis of Dec. 28 http://tinyurl.com/ypfshd.

> Demo 5 is a demonstration of why a Thevenin voltage source is much to be prefered over a simple ideal voltage source for continuous running circuits.

Ideal voltage sources are routinely and properly used in a great deal of circuit analysis. The problem with this transmission line setup isn't the use of perfect voltage source, it's that the entire system has no loss. Putting a finite resistance at the far end of the line, for example, results in a well-behaved system.

It sounds like you're confusing a Thevenin equivalent circuit with a voltage source in series with an impedance. All Thevenin equivalent circuits fit this description, but not all voltage sources in series with a resistance are Thevenin equivalents. I haven't used a Thevenin equivalent circuit in any of my analyses.

> Another way of illustrating the problem is to say that the ideal voltage source overwhelms any voltage from a returning wave. If an external voltage less than the initial voltage is applied to the ideal voltage source, vr = 0, vf = videal. If the external voltage exceeds the initial voltage, then vr = 0, vf = 0 This is a discontinuity, which shows up in Demo 5.

There are no discontinuites in the mathematical analysis. The forward and reverse waves always have a finite value or zero, and they always sum to the source voltage. No infinite currents or voltages occur. You can see from the program that the input voltage stays constant. (That is, it generates a sine wave of constant amplitude.) The only consequence is the oscillatory behavior of the line voltage and current.

> A third way of illustrating the discontinuity problem is to say that you can not apply a voltage to two wires that are short circuited at the input. In Demo 5, the reflected wave returns to find the circuit short circuited. On the other hand, the ideal voltage source applied voltage to an open circuit. We can not have it both ways.

Again, there is no discontinuity.

The demo 5 system doesn't represent anything that can be built in real life, and is basically just a curiosity. It was included mainly to verify that the program works properly under this limiting-case condition. It certainly has spurred some people to think about the meaning of perfect sources and reflection coefficients and revealed a lot of misunderstanding in the process, and I imagine it'll continue to do so.

In the scientific world it is a closed community and only within that
community can members create change. So you often hear that some very
clever people did not have their ideas examined until after they were
dead which can be a hundred years.Hams are a similar closed community
with respect to what creates radiation since they only accept books
and will not or cannot debate any alternatives.When in college you are
encouraged to debate which is way to retreat to the beginings and
build up a case in opposition to the opponent.This cannot happen in
ham radio because debates cannot happen except by those that deem
themselves as experts whose mission is to protect the status quo Thus
to become an expert one must follow the written word and deride those
that deign to question the status quo.When was the last to you read of
an open debate that was thouroughly discussed to a acceptable
conclusion? Well you haven't heard one because when two heads debate
one will always use personal attack as a means of retaliation.And I
mean always.
There is one discussion on this newsgroup that has gone on for several
years
and thousands of postings about travelling waves which I for one
consider them to be ficticious
in a resonant system. Do you ever believe one side or the other will
demonstrate the concepts

so all are on a common stage.? Hell no! Personal attacks were started
years ago in an attempt to cut down the debate and all must resign
themselves that the instant experts will defend the status quo for
ever. Will we ever see a painter sell his paintings for millions while
he is still alive?
Such is life! Such is death!

I just looked the above title up on Google
Guess what! They show a graph of the magnetic wave
in a tipped manner which is exactly what computor programs show for a
radiator
in equilibrium. Shades of a diamagnetic field no less, which is not
the same as one seen when one uses non diamagnetic iron filings when
in junior high school.
These search engines are great since the evidence keeps piling up
where sooner or later the dam is going to break.Remember that guy who
came along with a NEC program that confirmed the tipped radiator. No
body challenged the results of NEC even when it opposed existing book
text! Why? They did not want to suggest that the books were in error
and thus would not debate the reults given independently.

vf1(t, x) means that vf1 is a function of (varies with) both t and x.
Change t and/or x, and vf1 changes. This is not phasor notation, which I
specifically avoided. It is a simple description of the voltage at any
time and position. Plug t and x (and w, which stays fixed for the whole
analysis) into the argument of the sine function, poke it into your

pocket calculator, hit the sin key, and you have the voltage at that
time and place.

(Link http://campus.murraystate.edu/tsm/tsm118/Ch6/ch6_5/ch6_5.htm)

There are only two brief illustrations of a phasor (figs. 6-25 and 6-26)
in that document, which is otherwise just fine. The remainder of it is a
discussion of time functions like I've used.

> The sum of "wt" and "x" denote the phase angle of the wave, measured in
> degrees, both referenced to zero. Two angles are needed, one to represent the physical
location of each wave as a function of time, the second to locate the point of examination
of the wave. "wt" locates the wave in time and physical space . "x" locates the examination
point in physical space (on a transmission line in this case).

That's correct except for the description of wt. wt does not describe
the location of the wave in any way - it only tells how the value of the
wave changes with time. w converts the time, in seconds, to an angle in
radians which the sine function can be applied to.

> How is "x" located on the transmission line?

x is the distance from the input end of the line. It should be in the
same units as wt. I rather carelessly specified that it be in electrical
degrees, but that would be only if wt is also converted to degrees.

> My automatic assumption was that "x" was based at the input to the
> line. Thus, if the input was on the left side of the page, the line
> would extend to the right, and x would become larger when moving
> right.

Yes, that's correct.

> This led to a contradiction when I considered how the wave
> reflects from the right side upon encountering a discontinuity.
> Suddenly, a positive reflected wave represented by sine(-x) was made
> sine(x) at an open circuit. At position sin(90), the wave reversed and
> became sine(-90). It was if a factor of -1 was applied to the
> analysis, which was not the case here.

The change from -x to +x is due to the change in direction of
propagation. The input end of the line is at x = 0. In the examples, the
line is an integral number of wavelengths long, so the far end of the
line is x = n*2*pi radians (or n*360 degrees) where n is an integer. So
at those points, sin(wt - x) and sin(wt + x) are the same value.

> After considerable thought and time, I realized that the origin of "x"

>
> Think of the sine wave as an curve traced on a MOVING sheet of paper. The paper/curve moves in the direction of the forward wave. As the sine wave trace passes the zero point, the wave has a(unit) magnitude, described as sin(wt). Pick any wt and match wt to 0 on the physical scale. Then go to the x location of interest to find the magnitude of the sine wave at that location for one instant of time (wt).
>
> If a reflected wave is present, think of the same wave picture but moving in the opposite direction. When the reflection point is an open circuit, the reflected wave is generated by the forward wave so the two waves will always have a 1 to 1 corespondence at the zero point (point of reflection). The two waves are related by
>
> For the forward wave, vf(t, x) = sin(wt - x)
> For the reflected wave, vr(t, x) = sin(wt + x)
>
> For the total voltage at any point (open circuit case).
> vtot = vf(t, x) + vr(t, x)
> = sin(wt - x) + sin(wt + x)

This looks ok so far, but with x = 0 at the input end of the line, as I described. Let me show you -- start TLVis1, demo 1, and pause it just as the initial wave reaches the end. (The line is two wavelengths, by the way, not 3 as I incorrectly said in my introductory posting.) You've stopped it at wt = 4*pi radians, or 720 degrees, using a frequency of 1 Hz for simplicity. (I'll use degrees since most of us think better in degrees than radians.) What is the value of the voltage 1/4 wave from the input end of the line (x = 90 degrees)? sin(wt - x) = sin(720 - 90 deg.) = sin(-90 deg) = -1, which you can see is correct. What's the value 1/4 wave from the far end of the line (x = 630 deg.)? sin(720 - 630) = sin(90) = +1, which you can see is also correct.

Now start the analysis again and run it until the reflected wave reaches the source, and pause it again. You're now at wt = 1440 degrees. What's the value of the reflected wave at x = 90 degrees, that is, 90 degrees from the input end of the line? sin(wt + x) = sin(1440 + 90) = sin(90) = +1. 90 degrees from the far end (x = 630 deg), the value is sin(1440 + 630) = -1. These are what what the graph shows. You'll find that at every point, at every time, the value of the forward wave is k * sin(wt - x) and the reverse wave k * sin(wt + x) with x = 0 at the line input. (k changes at each reflection). Please let me know if you see any time or position for which this isn't true.

> When the reflection point is a short circuit, the voltage becomes zero at the short. The sum of forward and reflected wave voltages (at the short) will always be zero.

That's correct.

> Mathematically, this is accomplished by multiplying either the forward or reflective part of the equation a factor of -1.

It's done by applying a reflection coefficient of -1 to the impinging wave to result in a reflected wave which is equal and opposite in phase.

> The effect is to shift the phase of both forward and reflected waves by 90 degrees for a total of 180 degrees.

No. The analysis using superposition treats the forward wave and reverse waves separately. Reflection has no effect on the forward wave, and it creates a reflected wave. The reflected wave is the inverse of the forward wave if the reflection coefficient is -1.

We will apply the factor of -1 to the forward wave to maintain polarity consistancy with the open circuit case.
>
> vfS(t, x) = -sine(wt - x) For short circuit reflection.

I'm not quite sure what you're doing here. If the impinging wave is sin(wt - x), the reflected wave is -sin(wt + x) upon hitting a short circuit. If the impinging wave is sin(wt + x), its reflection is -sin(wt - x).

> Notice that if x = 0,
>
> vtotS(t, x) = -vfS(t, x) + vrS(t, x)
> = -sine(wt) + sine(wt)
> = 0
>
> For practice, let's analyze a transmission line fed at one end, open at the other. The relfections will have a voltage equal to the forward voltage at all times so we will use the equation
> vtot = sin(wt - x) + sin(wt + x)
>
> Assuming one volt peak for the sine wave amplitude (a unit amplitude), find the voltage at points vtot(wt, x),(0,0),(90,0),(180,0),(270,0),(360,0). Notice that every voltage will be computed at the reflection point, x = 0.

I'm not sure, but it looks like you're analyzing the sum of one forward and one reflected wave, at the far end of the line. At wt = 0, there is no voltage at the far end of the line. Perhaps you're also referencing the time to the reflection point, that is, t = 0 is when the wave reflects?

> For 0,0, vtot(wt,x) = sine(0 - 0) + sine(0 + 0) = 0
> For 90,0 vtot(wt,x) = sine(90 - 0) + sine(90 + 0) = 2v
> For 180,0, vtot(wt,x) = sine(180 - 0) + sine(180 + 0) = 0
> For 270,0, vtot(wt,x) = sine(270 - 0) + sine(270 + 0) = -2v
> For 360,0, vtot(wt,x) = sine(360 - 0) + sine(360 + 0) = 0

Those are correct values. You get the same result when you measure x from the input end of the line and time from when the source is turned on.
>
> In this example, one complete sine wave cycle has passed the x origin.

By which I believe you mean the far end of the line.

> For the next example, let's assume we want to compute the voltage at the point located 45 degrees from the reflection point at the same time that the voltage at the end is at a maximum. The maximum points for voltage at the end occurs when the 90 and 270 degree phases reach the reflection point. Lets look at the 90 degree case.
>
> For 90,45, vtot(wt,x) = sine(90 - 45) + sine(90 + 45)
> = sine(45) + sine(135)

> = -0.707 + (-0.707)
> = -1.414v
>
> We can continue this process to find the voltage envelope for any location/phase relationship desired. It works equally well for the short circuit case.

Where this would run into trouble would be on a line which is not an integral number of wavelengths long.

Certainly, you could use any point on or off the line as the x reference, and any time t as the t reference, as long as you modify the equations appropriately, as I believe you've shown. Your equations have reversed the sign of x and the roles of forward and reflected waves, to arrive at the same result when the two are summed.

The equations I presented use the input end of the line as the x reference and the time of source turn-on as the t reference. The equations were simpler because of the chosen line lengths, but apply to all line lengths when the appropriate phase terms are added.

This is an interesting alternative analysis. Is there any point on the line at any time for which it predicts a different result than my analysis? Does it correctly show the voltage of each forward and reflected wave individually as well as its sum? If so, then it's an equally valid analysis for this condition of integral wavelength lines.

If I get the time I'll try to extend either the analysis or program, or both, to non-integral-wavelength line lengths.

> There are no discontinuites in the mathematical analysis.

Maybe this is the source of a lot of confusion. If the Z0
of a transmission line changes from 50 ohms to 300 ohms,
that *IS* an impedance discontinuity. Any change in Z0
IS an impedance discontinuity, i.e. not a constant Z0.
Only a constant Z0 is not an impedance discontinuity.

EZNEC seems to be reporting the envelope,
not the instantaneous values but that is
sufficient for what I am trying to prove.

"Trying to prove"? Shirley, you jest. What
I am saying was proven more than a century
ago. What the heck has happened to the US
educational system since I went to Texas A&M
during the 50s?

The differences between standing-wave antennas
and traveling-wave antennas have been understood
for more than a century. That there is so much
ignorance exhibited on this newsgroup is not my
fault.

Chip Angle, N6CA, presents some very interesting ideas for a 50MHz noise cancelling system at: http://tinyurl.com/22gqab

The circuits for phase adjustment, gain control and summing (cancellation) should all scale easily to HF. However, the noise can only be cancelled completely if it behaves like a signal originating from single point. Noise from power lines may be arriving with a spread of amplitudes and phases.

To add to what PA3DJS has observed:

I have seen the use of near-field measurements to determine directivity and gain at the (then) NBS in Bolder, Col. A huge x-y table was used to move a probe over the face of an energized microwave antenna. Lasers (with cycle counters and mirrors) were used to measure the actual coordinates of the probe! A staggering amount of data was collected over a long period of time and then digested over another long period of time. This was done inside of a very large building where reflections were minimal.

To use this technique at, say, 10 MHz with a yagi would be improbable, but not impossible.

>
> Where this would run into trouble would be on a line which is not an
> integral number of wavelengths long.

No, it would work for any line length. The line length is the largest x value picked. For instance, to see the voltages at 597 degrees for a line 597 degrees long, make the x line at least 597 degrees long. Because the phase completely rotates every 360 degrees, a line 597-360 = 237 degrees long will have the same voltage relationship.

Assume we want to compute the total voltage at the input when the input is at peak applied voltage (as if from in ideal source) at +90 degrees. Using the 597 degree long line, wt at the end of the line will be 90 + 597 = 687 degrees. We are examining the line at 597 degrees so x would be 597 degrees.

For 687,597, vtot(wt,x) = sine(687 - 597) + sine(687 + 597)
= sine(327 - 237) + sine(327 + 237)
= sine(90) + sine(564)
= sine(90) + sine(204)
= 1 + (-.406)

= 0.594v

I hope you come up with the same value.

Not that I know of. I think you are not really using x, but x plus line length in your equations. This continues to have me confused.

> Does it correctly show the voltage of each forward and
> reflected wave individually as well as its sum? If so, then it's an

So far as I have tested, yes. There is no reason to use the reflection point as the reference unless it simplifies the equations or improves understanding.

>
> If I get the time I'll try to extend either the analysis or program, or

Using the reflection point as the zero reference seems to correspond with an observation you made about the end of the line controlling the SWR.

OK. Thank you for your patience. You said "The SWR on the wire is load-
based and is equal to 8:1 as evidenced by CURRENT on the wire. :-)

You cannot make a SWR measurement on a receive antenna any other way."

My very simple question: How do I measure that ISWR current?

Please describe possible meters and probes and where on the receive antenna
do I measure this current? At the input? At the nodes? At the zero crosses?
How do you calculate ISWR? Is it Imax/Imin? I am only trying to
conceptualize what you mean. Do you have to block the reverse current
somehow and measure forward current and vice versa? What does this do to the
standing wave? What does any direct current measurement do to the ISWR
itself?

Hi Dan,

Well, in fact I don't recall having said anything about "Load-Based,"
but it is immaterial to your question(s).

>You cannot make a SWR measurement on a receive antenna any other way."

You are still trapped in a loose thread of associations.

We will get back to that in a moment (I hate doing this, trying to
intuit what you are after). The specific comment you recite above is
wholly out of context, and is being joined to a new one. This is why
I ask you to strip out the noise and ask the question that is
bothering you.

>My very simple question: How do I measure that ISWR current?

Specifically, as you have already suggested, with a loop pickup.
However, in my career I have never encountered its use as a precision
device when measuring voltage is so much easier. EZNEC does not
report voltage (although it could be computed, I will leave that to
others as there is no significant information obtained in that
exercise).

>Please describe possible meters and probes and where on the receive antenna
>do I measure this current?

I've commented on that already. But this tied back into receive and
you will not find a satisfactory, bench answer for that which is
practical (in the sense of $).

>At the input?

For waves on a line you go to the line. EZNEC provides this quite
clearly and even provides a graphic solution if you are not into the
actual numbers.

>At the nodes? At the zero crosses?
>How do you calculate ISWR? Is it Imax/Imin?

That is the conventional way to observe Standing Waves.

>I am only trying to
>conceptualize what you mean. Do you have to block the reverse current
>somehow and measure forward current and vice versa? What does this do to the
>standing wave? What does any direct current measurement do to the ISWR
>itself?

Dan, you've got yourself wrapped around the axle and here I have to force a solution to your problem that you only vaguely offer through a chain of disconnected references above.

First, you spend an inordinate amount of effort quoting to the point of receiving, and yet none of your questions appear to be aware of the significance of receiving with these breed of (Traveling Wave) antennas.

Cecil's wire, one foot off the ground, is strongly influenced by its proximity. I demonstrated that. However, Cecil divorces this effect while embracing his goal of explaining away the confusion about Traveling Wave antennas. This one foot high monstrosity is most closely allied with the Beverage antenna which was developed with ground in mind and even here, Cecil corrupts this concept to turn his model into a Traveling Wave transmission line. In effect, his is a bait and switch argument as he abandoned the "explanation" 350 posts ago and never returned until I forced the argument.

Cecil, under protest to my proofs of Standing Wave on these Traveling Wave, then supplied a citation that heads this very thread:
>>"Because the Beverage is a
>>traveling wave, terminated antenna, it has no standing
>>waves resulting from radio signals."

It contains FROM radio signals. FROM is an externality. In other words the antenna must be externally excited to test the validity of this specific statement. Further, this statement has its own internal logic in that the antenna (the Beverage) is a RECEIVE antenna. Further, this statement has its own internal logic in that a Beverage antenna employs ground as an active element. Hence, all internal logical characteristics are consistent with the statement about externality. Any reference to source SWR is wholly inappropriate.

EZNEC is perfectly capable of measuring a receive antenna, if you can supply an antenna to excite it. I did so explicitly. The reports offered by EZNEC will give you a source SWR reading like Cecil quoted, but that is entirely unrelated to the receive antenna performance. I did not report that reading for that reason, Cecil did - for whatever reason, but a reason that bore no relation to Standing/Traveling waves on the test antenna.

EZNEC will report all currents on all wires everywhere. When the Beverage is excited by a source 100 kilometers away, those currents in the wires defining the Beverage exhibit classic Standing Waves. This is quite simple.

Now as to your enquiry in how to measure those currents. That is not practical at the nanoAmpere levels, but software does it quite easily. If I were tasked to do it, I would immediately transform this into the voltage model, modulate the source with an unique pattern, and perform a synchronous detection of the levels involved along the length of the line. A trivial concept that is difficult in practice.

Now, I have pounded out a lot of words in an effort to eke out your question. Was it answered?

Yes, that would help if hams were intersted but they are not.They do not agree that a diamagnetic field is different to any other field and the ham radio books will not tell them otherwise. Look at the simple math of adding a time varient field to Gaussian law makes it exactly the same as Maxwells law.but hams will not accept the math. Is it any wonder that manufacturers are going overseas for engineers because american education is one of rote. If you add up the post graduates working on research at any american university foreign graduates out number american students. Micro soft wants more engineers , not from America tho. As far as the URL it was the first one on the list If hams were interested in ham radio for other than only talking they would have no problem finding it. Fact is that they have no idea what a diamagnetic material actualy is or why they should care. I doubt that it is even mentioned anywhere by the ARRL.I wonder why you are checking things out,as an engineer you should be aware of the facts already.Not one ham on this newsgroup could verfy the shape of a diamagnetic
field wth respect to current flow. Yet all consider themselves as competant enough to describe a bouncing wave even tho they don't know the qualities required for a radiation material.

But I think this is a very difficult point for many, even physicists and engineers who do not deal with it often.

People need to understand the huge difference in the 2 waveforms that you present. The traveling wave (1st equation) is an oscillating cosine function in the normal sense where phase changes can be measured. It "travels" down the wire dustance. The "Io*cos(kx)*cos(kt) describes a fixed envelope over distance, of oscillating cosine functions over time, that does not travel (move) over the wire distance...it literally "stands". Some people somehow measure the 'delay' in a standing wave because they think they see a "phase" change. There is none. But once you get past the zero crosses theire will be variations in amplitude with time, at whichever point the standing wave "stands". Obviously that has nothing to do with phase changes.

I don't understand a lot of this talk about waves bouncing which is
fortunate. Icould not possibly stay on a thread where everybody is
talking past each other and then changing the subject as they didn't
understand the subject in the first place. In ham radio nothing is
believed if it is contrary to the norm.This bouncing wave thing will
never come to closure as all participants are deaf. As far as me
getting involved all the answers involved in my description of radio
are known facts in the scientific world and fully coroberated. Heck
they are even corroberated by existing antenna computor programs and
actual tests. I can't see how these waves fit in with classical
science so it must be another invented science that it referes to. Now
if the trend changed to debate the voracity of existing accepted data
is proved to be incorrect then they would have my attention but the
group is not competant enough for that trail.
Regards
Art

> Think of the sine wave as an curve traced on a MOVING sheet of paper. The

> paper/curve moves in the direction of the forward wave.

Try this:

Pick a distance x = pi/3. Now take the sheet of paper perpendicular to the dipole wire. Move it at a constant velocity in the perpendicular direction with a pen recorder tracing the magnitude of the voltage on the antenna to the paper as it moves. There will be a cosine function drawn on the paper.

Given: I = Io*cos(kx)*cos(wt)

At pi/3 radians, cos(pi/3) = 0.5

The cosine function drawn on the paper moving at right angles to the antenna will be:

I = 0.5*Io*cos(kt).

Now move the paper to x = pi/2.

cos(pi/2) = 0

The function drawn on the paper will be I = 0.

Now move the paper to x = pi

cos(pi) = -1

The function drawn on the paper, at RIGHT ANGLES tio the antenna will be:

I = -Io*cos(wt)

That is how a standing wave operates.

The purpose of pointing out the trigonometric relationship between the
sum of sines and the product of sine and cosine was to illustrate
that, contrary to your assertion, there isn't a difference in the
waves. The traveling waves can either be written mathematically as
two separate traveling waves, or as one standing wave. It makes no
difference; the waves are the same in either case irrespective of how
you choose to describe them mathematically. Do you grasp the meaning
here, or not?

Thanks,

ac6xg

As a general rule, the voltage can't be computed because of the spacing between the wire and whatever reference point you're measuring voltage to. The voltage depends on the path taken between the two points (conceptually, how you arrange the voltmeter leads), so there's no single answer. That's why EZNEC computes only current.

This is also one of the several problems with treating an antenna like a transmission line. The similarity between the two is just enough to tempt people to take the analogy farther than it holds.

Well, you said the only way to measure SWR on a receive antenna is by measuring current (sort of as an aside). I wanted to know the significance of that. Now I know that the reason you said that was to support your SWR calculation for a receive antenna using EZNEC, which is based on current (method of moments). You were not saying it in terms of making physical measurements but only to support the accuracy of your statement (i.e. there's no better way to determine SWR on a receiving antenna than to measure current, and, EZNEC is based on current). I know this was not your main point, it was just an aside, but I don't agree with it; however, that in itself does not diminish your main point.

You are a mechanical engineer, right? Consider acoustic "radiation". Pluck a guitar string; the fundamental wavelength of the sound your hear (and its harmonics) will be related to the length of the string and the speed of the wave in the string (not the speed of sound) which depends on the tension and density of the string. f*length = v. The 'radiation resistance' is the string's standing wave pushing against the air and producing sound energy from applied kinetic energy stored in the *vibrating string*. The musical note you hear does move at the speed of sound. This is somewhat analagous to an antenna. Now I agree that to be a musician it is not neccesary to understand these principles but to design guitar strings (antennas) it would be advantageous to understand it (though not mandatory). In order to discuss the reasons why certain guitar strings work better or sound different than others, it is essential to understand this and to understand it, you must first understand what an acoustic standing wave is. You are working on an antenna model; you may be a ham and you may even be designing antennas but you do not know how standing waves work. It is not compusory. You can still operate and design antennas without knowing how this works. But, it sounds like you need some more tools. You are dealing with EM fields and waves and you are also dealing with vibrations of particles making your model, if it works, almost as related to a mechancial wave as an electrical wave...a combination of both? I think on the track that you are on, which is not real clear to me, I would advise getting out the physics books and getting familiar with these concepts...they are not only EE related, there is an ME analog (as there often is for fundamental EE problems).

Art wrote:
"I wonder why you are checking things out, as an engineer you should be aware of facts already."

A fact is a reality. An opinion lacking credible testimony is not a proven fact.

Wave tilt is a known phenomenon. A wave traveling along the surface of the earth is slightly slowed by the earth, so it seems to tilt slightly in its direction of travel, like "dragging its feet".

A wave reflected by grazing a surface has an angle of reflection equal to its angle of incidence. An incoming wave reflected by the ionosphere has a tilt with respect to the horizontal.

A Beverage antenna can be as simple as a wire supported at low altitude above the earth, and a seeming paradox is that although horizontal, the wire is sensitive to vertically polarized waves. Despite Art`s questioning that hams would know about wave tilt, an ARRL publication, ON4UN`s "Low-Band DXing", begins its chapter on Special Receiving Antennas with the Beverage.

Most engineers in this newsgroup are well aware of the facts needed in their profession. One particular mechanical engineer is claiming new discoveries without sufficient supporting information.

Best regards, Richard Harrison, KB5WZI

I understand that a diamagnetic field is oriented differently to the
norm
Thus a diamagnetic field on a radiator is different to the norm.
This I see as the lynch pin of radiation. Hams do not recognise what
science has found for some reason. There is not a physics based ham on
the group that will explain this type of field
and it was not known by Terman so the dark ages persist. Also I claim
no new discoveries. Every thing I have described is documented on
Google which you do not have the ability to check out....Tough.You
don't know how to use an antenna computor program so you can't see
tilt for your self. You are in sad shape.If you can point to anything
that I stated is NOT fact
then speak up with the details and share with the group

Thanks for the examples. You use the term "I" which is usually the current, but the math makes sense for voltage.

To find the distance x = pi/3, I assume you mean from one end of the dipole, back toward the dipole center?

As cos(wt) rotates between 0 and 2pi, cos(wt) moves between +1 and -1. The voltage will always be the negative of the initial voltage times the cosine of the instantaneous angle wt.

Maybe (I might have reversed them). But it doesn't matter for the concept.

Right, at pi radians, I moves between 0 and -1*Io. At that point, the
standing wave is always zero to negative reaching a minima at -1*Io. Here
the wave "stands" at its minimum point. The "envelope" of the wave is -1
negative; it oscillates over time between 0 and -1*Io at frequency w.

"Cecil, Can you help me understand that the end of a dipole is an open
circuit?
Nothing falls out because the current changes direction ala AC because
the end of a dipole equates with the time that requires the current
changes direction. So where is the open circuit? I also cannot see why
radiation reduces reflection if the circuit can be completed with
iron!"

OK Cecil, I'm waiting for your answer on this one! ;-)

Yanno? That was a vague response, the above ...

What I meant to say is, YES! I worry that "in close" measurements with my field strength meter are/is inaccurate--and, I am ignorant on how to correct this (without going to far-field.) Indeed, it can easily be proven this is the case, EZNEC gives much different results than those plotted with a "close" field strength meter--has anyone found different. If so, I am GREATLY interested, and what am I doing wrong?

Sometimes it is just good to ask ...

Warm regards,
JS

Get yourself a portable VHF radio that receives AM and use a handheld Yagi to trace down the noise. Powerline interference is much easier to DF at VHF. Pull the main breaker on your house to make sure the noise isn't being generated within your residence. Here in the USA, the power companies are obligated to eliminate interference emanating from their equipment, but don't know about ZL. It never hurts to ask. The power companies up here have very skilled folks who track down powerline interference complaints.

Good luck with finding the source.

That was an ignorant mistake. Like a rank novice, Richard assumed
a 50 ohm SWR but the antenna is *NOT* a 50 ohm antenna. The
acutal SWR is barely above 1.0:1.

That was a quote from one of my references. But I suspect
that a Beverage antenna must be excited in its directional
dimension for that to be true. It probably would have been
more accurate to say it has no reflections rather than to
say it has no standing waves.

Jim Kelley wrote:
> The purpose of pointing out the trigonometric relationship between the
> sum of sines and the product of sine and cosine was to illustrate that,
> contrary to your assertion, there isn't a difference in the waves.

Jim, please go ask the head of your math department if
there's any difference in those equations. That you don't
see any difference is just extreme ignorance on your part.

Set cos(kx-wt) = cos(kx)*cos(wt) and wrestle with the
trig identities until you alleviate your ignorance.

You are extremely wrong and ignorant of mathematics.
You will realize that fact when you are unable to
prove your assertions even to yourself.

Hint: cos(kx+wt) = cos(kx)*cos(wt) - sin(kx)*sin(wt)
You are obviously missing half of the terms when you
say there "isn't a difference in the waves". (FYI,
anyone who knows anything about mathematics is laughing
at you.)

Just because the voltage is hard to measure doesn't mean it
isn't proportional to the E-field.

> OK Cecil, I'm waiting for your answer on this one! ;-)

The end of a dipole is like an open circuit transmission line.
The traveling wave hits the open-circuit and is reflected.
The forward current and reflected current are equal in magnitude
at the end point and 180 degrees out of phase. Therefore, the
current is zero. That's logical.

The forward voltage and reflected voltage are in phase. Therefore,
the voltage is at a maximum at the ends of the dipole. That's known.
That voltage can be calculated to a certain accuracy.

At the feedpoint of a dipole, the forward wave energy is about
20% higher than the reflected wave energy. That 20% difference
between forward wave and reflected wave is the amount of power
lost to losses and radiation.

A #14 horizontal wire 30 feet in the air has a characteristic
impedance of 600 ohms. That's all you need to know to perform
the voltage and current calculations for a particular power
input to the antenna.

>in itself does not diminish your main point.

Hi Dan,

It is merely a response to the "framing" of a specific expectation
within the context of Cecil's citation. The citation demanded an
externality, I supplied a stimulus external to the antenna.

However, this does not mean that there is no other indicator of
Standing Waves on a Traveling Wave antenna, and it does not make this
exotic testing the only proof of Standing Waves on a Traveling Wave
antenna. There is, after all, the concept of reciprocity.

If you look at the reciprocal actions offered by exciting a Traveling
Wave antenna with a source directly attached to it (and Cecil's last
example proves this), you find Standing Waves. This may confound the
SWR meter, but then that meter doesn't indicate what is on the wires,
it indicates what is impressed upon the finals.

Now, if you want to discard EZNEC (which for some odd reason you seem
to approach method of moments with a sneer), conventional methods
would still bear out the same results. Lord knows I've sat at the
bench doing it the conventional way for thousands of measurements.
I've probably made more physical measurements in a day, than anyone
here has in a lifetime.

Others, don't bore us with indignities about all your SWR meter
readings in reply to that last statement. :-)

So now to the shoe you dropped:
> I know this was not your
>main point, it was just an aside, but I don't agree with it

What was my main point, and how is yours conflict with it? Is yours a
philosophical triviality so common to these threads, or does it come
with physical measurements experience?

Hi Stewart,

Take your DC off the battery post, not the distribution system (but
make sure to fuse that lead). The bonding you speak of is
prinicipally for RF feedback, and ground loops up in that region;
alternator whine arrives through the DC feed.

There are two parts to the TV antenna which cover two bands. Separate
elements for each band, but all on the same boom.

Art, here is where you make a huge mistake. You are bringing personal "feelings" into the equation. Who really gives a whoop doop dingle about feelings?

With your Mechanical engineering background, I assume that you must have sat in on design and other meetings. Many of the ones I have sat in have become plenty heated.

So What? We leave the meeting and go get the job done. Then we enjoy a beer with the people we were arguing with after work.

Respectfully Art, there are people who will not ever hold with ideas that are considered mainstream. If *their* alternative ideas were accepted as fact, then there is an excellent chance that they will abandon them and move on to something else. This is especially true if feeling somehow come into their science. I see this fairly often. Politics often comes to mind, in which one group is excellent at castigation, pointing out example after example of others wrongdoing but when in power, they seem to not be able to effectively function.

IOW, is the rebel right because they found out something new, and can promote the idea, or are they right because they are a rebel?

> Personal attacks were started
> years ago in an attempt to cut down the debate and all must resign

Hi Stewart,

There's no reason for filters, the battery is already the biggest
capacitor in the world - for all practical purposes. Also, the
regulator disconnects it from the alternator 5 minutes after you've
started the car.

I am not so confident that the lead cell battery (or any battery) is a replacement for a filter. A battery demonstrates about 75 to 85 percent efficiency for charging and discharging, but a capacitor is just under 100 percent efficient. When used as a filter, a battery is a capacitor with a series resistor.

Battery efficiency is probably less at radio frequencies.

The regulators that I am familiar with do not disconnect the battery from the alternator. They reduce the alternator field current so that the alternator output voltage is reduced.

Things changed when the influx of CBers came into the hobby. As
president of the local club it was my job to welcome them despite the
animosity that was floating around. After 5 years I quit
and watched as ham radio went down hill so I also quit getting on the
air.As Age crept up on me
I could not play around with mixers anymore so I chose antennas which
my eyes could handle.
I then got insulted when I shared what I was doing on this group as
were my patents. I got so many insults that I even dropped one I had
just applied for and left this newsgroup. I still carried on with my
work and some years ago again shared it with the group. Insults
immediately started coming thru without examining that I was
sharing.But this time it is different. I am not going away even tho
hams are not interested in new ideas and in fact push them away. True
my writing gets worse as I age which is a sorry state of affairs butI
am not willing to fade away. I WILL HANG ON AND STAY.I worked hard
during the night scouring the internet to find a link that would
explain part of the things that I talk about and which all reject and
apply insults.
I finally found a suitable site that also came with diagrams to make
it easier to understand.
It will be on another thread so please read it. If it is of interest
then you will see I am not blabbering.Never the less I am willing to
share the rest of my work with true radio amateurs that have the
manners that are required for a suitable discussion or debate.

Hi Roger,

My experience across several cars tends to indicate it is an excellent source. I have never used filters except once in the 60s and even then it was a poor solution.

>When used as a filter, a battery is a capacitor with a series resistor. A very, very, very small resistor.

The practical matter of this, is that it is far easier and cheaper to simply make the connection to see if it does the job, instead of investing in a filter that might not work.

Cecil,

There are an infinite number of different functions one could write to describe an infinite number of different possible wave shapes. And none of them would necessarily be mathematically equivalent to another. But when you write the equation for the superposition of traveling waves and claim that resultant standing wave is a different kind of electromagnetic wave, that is a misguided point of view. The equation for a standing wave is simply a different way of writing the sum of two traveling waves. Being that there is only one kind to chose from, there cannot be a different kind of electromagnetic wave. Is it impossible for you to acknowledge this simple point in a gentlemanly fashion?

> You are extremely wrong and ignorant of mathematics.

Any 'extreme wrongness' notwithstanding, what I don't know about mathematics could fill a book. On the other hand, you almost inevitably end up lying and turning technical discussions into personal attacks. Ask anyone.

STOP STOP STOOOOOOOOOP RIGHT THERE
Thank you Lord for this opportinity you have given meto bring Ham
radio back to reality after Terman went to heaven
Gentleman this is a relativistic statement where Einstein tried to get
a unification theory
\before he died. He failed.You all know your houses are wired for AC,
usually a ring circuit.
Yes 50/60 is frequency just like 10 metrrs. Now go homw and cut the
wire in the kitchen to make it an open circuit Now ham r5adio says the
cuyrrent will turn around where you cutt it and it will go back. Well
science has not seen a trace of this new frequency of 100, 110 0r 220
line double its frequency to twice what it was before. On top of that
the lights went out on the circuit before and after the wire was cut
which means the current stopped when it was cut.
Same for a antenna which usually has a higher frequency. No the
current does not turn back or fall of the end. Right from the get go
the current knows that it must travel forward regards until the time
of half a period comes about. It cannot turn around and collide with
current that is obeying the rules. When it first started its travels
up the radiator the current travelled on or above the skin that
encloses the conductor knowing it can only referse at a specific
time. When the current6 reaches the top it will turn around if the
time alloted has also exspired. If this hasn't happenned it sees that
the inside of the antenna has nothing but decaying particles on its
inside which is really just a resistor. The current flows down the
center of this resistance. True it is not radiating at this point as
it is on the wrongside
of this decaying skin. Fortunately forward time expires just at the

time the current reached the bottom end of the radiator at the same time half a period expired. So the current retraces its path up the center and down the outside of the antenna where it can again radiate. It reaches its starting point at exactly the same time as two haf periods have elavsed which is one cycle. Yes the cuurent traveled a full circuit which it must do as we know current flow today. No open circuits and no current flow each and every way because it was forced somehow to change direction and ofcourse all the lights went out.

All of this started because physicsts could not reconcile the laws of electricity or Maxwell with those of Newton and ofcourse Gauss. This thinking continues to this day even tho Einstein died without proving things. Was this thread really worth it just to carry on the legacy of Terman and Einstein regardless of the facts? Now look at the URL i have supplied on another thread and note how a diamagnetic field is somehow different from what you have been taught.
Note especially that the lines of force do not follow the same direction that you expected.
If a paricle gets carried by these special lines of force the particle becomes ejected AWAY from the field. Now.Is all this "blabbering" or is it worth pursueing in the absence of Einstein? Can't we get back to classical physics that the masters of which Newton, Maxwell and Gauss stood on the shoulders of. Their science and our science is the same. Let us not kick the legs from under them by inventing new sciences so that our difficulties in understanding can be resolved.
Read the URL PLEASE .
I have found for you a description which also has picture as well as words and mull over the implications of what I place before you.

how do you measure 'power'?? you don't. and no swr meter in the world
measures 'power'. they all take samples of voltage and/or current and drive
a simple meter circuit that just happens to be calibrated in units of watts
because thats what most users of cheap meters want to see. they could just
as easily be calibrated in volts or amps referenced to 50 ohms

If I directly measure I or V, that is one thing. If I measure I**2 or V**2,
which I must for power into 50 ohms, that is something else. Thus, the way
that the meter is graduated is of prime importance. Either I have a meter
whose circuit directly measures the delta of I**2 or V**2 into the antenna
with linear scale, or it indirectly measures delta I**2 or delta V**2 by
squared graduations on the meter scale/ In all cases, it is still measuring
power. So I do not understand the point. I have not seen a meter that
appears to directly measure the ratio of Vmax forward/Vmax reflected or Imax
forward/Imax reflected, which *would* be a direct SWR measurement.

Hopefully this url will get you to what I want you to read.
Read, think for your self and then decide why the use of
aluminium is relavent to our hobby. I have also placed an
abstract on the forming of radiation on E Ham forum to get
as wide a distribution as I could. Hopefully this will a new
beginning for ham radio. Also get an optimiser computor
program to obtain the tipping angle of a radiator for your self.
Google for information every time you are unsure. For goodness
sake don't guess but follow the lead of present day science.
Somebody will burst out without reading or thinking.
Is that person going to be you?
Very best regards
Art Unwin.....KB9MZ.....XG (uk)

The NEC program is just a computer model, for discussion purposes only. I think there are far too many variables in real life for the program to take into account. It may be valuable but I am not yet convinced it is infallible.

> Lord knows I've sat at the
> bench doing it the conventional way for thousands of measurements.

That is the only way to do it in my opinion. I am not very convinced that the NEC models can be used as a first source to support any proposals in these discussions although they are useful as a secondary level of corroboration. Although we accept them because we are usually too busy to perform hardware measurements, at least one should consider exactly how one "would" or "could" make a hardware emasurement in real life. The less likely you are able to measure in real life, the more likely your proposal is heavy on abstractions and light on reality. For example. I think the more significant recent developments in quantum theory, such as "string theory", although they may attract a lot of research dollars to fund professors at our Universities, are actually quite useless in practice because no one will ever be able to prove it true by empirical measurments. I can say "God created the universe" which may seem plausible until I am challenged to prove the existence of God, which I cannot now and never will be able to do. Belief requires faith or even a suspension of logical thought, neither of which I am prepared to do for science.

You were arguing about an SWR on a NEC model being 8:1, due, I have heard, to an erroneous assumption of Zo. No problem with me. But when you made an

assertion that I thought could not be measured easily, I hesitated to take it true using faith based science. As you can see, the NEC model falls apart by making one simple erroneous assumption. Or was it? You can argue about that. That is the problem with these models, nobody is so intelligent that they are free of errors and no model is infallible either.

The delta between what is sent forward and what is reflected back. If the
delta is zero, SWR = 1:1.

Oh my!
I wish I was as eloquent as you. You would explained the problem so
much better than I did. When an assumption was made in addition to the
use of Maxwell's laws it was to make the program conform with known
results. And then the assuption made regarding sino soidal current
flow was made is found to be in error, thus the absolute validity of
the programs comes into question. Were they generated to follow
Maxwells laws explicably or were they made to reflect empirical
results? I suspect that Maxwells laws overode external human
influences
imposed by the programmer who are not infallable

SWR meters calibrated in watts? Really, where?

However, I do find it enough that my watt meter reads 2.5 KW and my
linear is 5 KW--loaded lightly to achieve the 2.5 KW. Somehow it just
makes sense ... and, I am running it into a dummy load--of course! :-D

>The NEC program is just a computer model,

Hi Dan,

"Just a" is a familiar dismissal for almost anything offered. Without corroborating evidence for the fear that is associated with its usage; then such an expression is a totem or religious chant to chase away spirits.

"Computer model"s are as useful as they are predictive. EZNEC conforms to NEC which in turn conforms to field tests. The chain of evidence is quite strong and I have yet to hear of any real-life design that has defied NEC analysis.

>for discussion purposes only. I
>think there are far too many variables in real life for the program to take
>into account. It may be valuable but I am not yet convinced it is
>infallible.

"Infallible" is a feeble demand to the gods for proof of their existence. I very seriously doubt you have ever encountered anything infallible in your life, so why start now? This desire for guarantee is usually a crutch for the turmoil of nervous youth.

A computer model is explicitly not "real life" except to the extent by which it is included as a parameter. You don't name anything in particular that troubles you about "real life," so you don't appear to be looking for assurance, just negation.

NEC has certainly responded to "real life" through the iterations of its successive designs (something that Roy may have more to say). There are explicit allowances for Ohmic loss of the conductor, and dielectric loss of insulation. Also added is the issue of the proximity of earth, and NEC offers similar parameter controls for describing it. In fact, you (or anyone) is probably far more ignorant of the characteristics of the earth in their "real life" than would be the problem of NEC to successfully model it.

As to this last statement, the problem with modeling is far more operator error borne than computer borne. If you have any suspicions, gripes, grief, or indecision, it can frequently be laid at the feet of the designer. That is why I use the designer's own designs to split open their logic to reveal the corruption. If the model lacks interior fidelity, it is not the fault of NEC.

Any review of EZNEC's help files will quickly reveal there are many trip points that can result in low accuracy, or outright errors. These can be investigated by simply asking for the model and examining it yourself. I revealed a couple from Cecil's offering: a strongly earth associated design modeled against a perfect earth; remote stimulus. I explicitly described changes of one or two parameters (expressly demanded by Cecil) and revealed that Traveling Wave antennas have Standing Waves upon them. This is hardly a monumental observation - except when it upsets the horse cart of celebrity.

If you want to remain unconvinced, that is a rather passive activity of low participation and little information. I would suspect that of the 6 billion inhabitants of earth, there are 6 billion like you, but they don't write here. Their motivations lie elsewhere where they participate in activities to their interests.

>> What was my main point, and how is yours conflict with it?
>
>You were arguing about an SWR on a NEC model being 8:1, due, I have heard,
>to an erroneous assumption of Zo.

Well, with nothing more substantial than that, this is not a particularly condemning point. You should note that you are trapped by your own passivity into accepting other people's "word for it." This is an odd position to be in when you are writing in a community of Modelers who exchange designs for review and can either confirm or deny claims against rather more substantial evidence than what was overheard.

>No problem with me. But when you made an
>assertion that I thought could not be measured easily, I hesitated to take
>it true using faith based science. As you can see, the NEC model falls apart
>by making one simple erroneous assumption. Or was it? You can argue about
>that. That is the problem with these models, nobody is so intelligent that
>they are free of errors and no model is infallible either.

You would stand to learn far more by examining the model yourself than have me swear on my credentials. You could stand to learn far more by asking for data instead of pondering the emotional chemistry of writing to a newsgroup, or second guessing how a model might fail.

Those that stand to lose the most in celebrity, rarely offer correlating data or respond in true faith to enquiry for details. This is, after all, the point of the exchange of correspondence where celebrities post merely to pronounce their claims a spark of invention to be validated here. That just isn't the way it works here, or in

"real life" either.

Hi Dan,

I was trying to untangle this expression from your statement:
>>> I have not seen a meter that
>>>appears to directly measure the ratio of Vmax forward/Vmax reflected or Imax
>>>forward/Imax reflected, which *would* be a direct SWR measurement.

How does you lack of exposure to such an instrument impact this
thread? Do you need it for assurance? Does it demonstrate something
lacking in other methods of determination? I've already written to a
method of determining not only SWR but the phase of reflections using
one meter, switched between three points along a line (or probed
directly). Such a method does not deny the accuracy of other methods
or reveal any more information.

In short, what significance is there in a "direct SWR measurement?" My
skill at it is hardly remarkable until you get to some rather obscure
situations (and a lot of what is obscure here passes as discovery of
the ages stuff, but those discoverers lack the skill).

> infallible. . .

Exactly the same can be said of any of the other models we successfully use daily. "Resistances", "impedances", "capacitances", and other objects we routinely use in circuit analysis, are "just" models of real objects. Likewise, the equations we use for solving all kinds of problems, including transmission line and circuit analysis problems, are "just" models of actual behavior. Ohm's law is "just" a model of the relationship among V, I, and Z. The fundamental equations relating currents and fields, Maxwell's equations, and all other equations used in engineering are "just" models of real behavior.

All models are subject to intelligent use. A person modeling a real resistor as a pure resistance at 50 GHz will get just as bad results as a person modeling a dipole on a circuit board in a smart key in a pocket as a free-space dipole. No model, not even a simple resistance, is infallible -- even it can be misused by someone not having the underlying knowledge necessary to apply it. So of course computer models aren't infallible either.

But there are many, many real life antennas which can be modeled with great accuracy with NEC. I use EZNEC regularly myself in my consulting work to design antennas, and find very good correlation with anechoic chamber pattern tests, network analyzer impedance tests, and performance results. So do the many aerospace companies, military organizations, space agencies, universities, research labs, domestic and international broadcasters, and many other companies that use EZNEC daily to help design real antennas that work as predicted. But those aren't the only people successfully modeling with EZNEC -- a large number of amateurs successfully use it also.

I'm not sure what it is that makes models inherently less accurate or believable if the equations are solved with a computer than if they're solved by some other method. Perhaps you could explain.

Your entire post seems to indicate that, in order to participate in this newsgroup, you must use EZNEC. Forget about all those tiresome formulae and the concept building; you need not know how a standing wave works or the mathematics thereof. I'm sure it was a boon for you when the slide rule was replaced by the electronic calculator, leaving your mind free from having to wrestle with the true science and mathematics that is going on with your engineering problems and just let the machine do it for you. If you make a stupid mistake, don't fret, somebody will correct the parameters and re-run the program until it fits. No need to understand maxwell, calculus, vectors, phasors, just let the program do it all for your using the brute force method of moments. Transistors are dirt cheap and efficient calculations are no longer necessary. No need for analog computers. Just plug it into a method of moments calculator and you are done.

What's missing with this, of course, is the part your grey matter is supposed to do. Grey matter can take a permenent vacation.

I see no problem using a NEC to confirm a calculation or concept. But you seem to advocate its exclusive use as the only authoritative, indeed, available, tool.

Of course, I disagree and think that rraa still has room for real math and scientific concepts and indeed there is room for NEC. However, if the choice is given to prefer one over the other, I prefer the former because creative design does not occur by arbitrary and random use computer problems such as NEC, CADAM and the like, it comes from scientific method which requires human thought.

I don't think you said quite what you meant.

There are many real-life designs which are beyond NEC's (and hence EZNEC's) ability to analyze. One common example is a microstrip (patch) antenna; NEC has no way to account for the dielectric. A user with even minimal knowledge should realize the significance of this shortcoming, and not expect to be able to get accurate results from a model with the dielectric excluded.

However, and I think this is probably what you meant, the accuracy of NEC is strikingly good whenever a model can be constructed that does a good job of mimicking the real antenna. All this really proves are two things: 1. The fundamental electromagnetic equations solved by NEC are sound, and 2. Most of the bugs have been worked out of the code, so it correctly solves the equations.

The equations solved by NEC can't be solved in closed form. That means there is no formula into which you can plug numbers and calculate a result. The method it uses can be done manually for very simple cases and with very limited accuracy -- see Kraus' _Antennas_, 2nd Edition or later, for a good example. A number of very simple antennas with simple geometry can be analyzed using approximations which have been developed over the years, but they're usually strictly limited to a narrow range of conditions. For example, there have been many methods developed for finding the input impedance of a simple, straight dipole of various lengths and diameters. (I have a large collection of papers and references on this topic, accumulated before MININEC became available.) All are based on approximations, and some are better than others at certain lengths and diameters. None are terribly good over a wide range, and bending the elements, for example, invalidates any of the methods. Now, why should we expect results from these methods to be better in some way than results from NEC, "just" a computer model, when NEC can solve the problem for any length, diameter, and shape, to an arbitrary degree of accuracy, in a fraction of a second?

The measurement itself will change the SWR significantly once you start
adding probes to the antenna.

Hi Dan,

No, it explicitly informs you that if you don't have any modeler, you
are only guessing. Modelers offer solutions that I doubt you could
obtain through your own efforts.

>Forget about all those tiresome formulae and
>the concept building; you need not know how a standing wave works or the
>mathematics thereof.

Forget? Well, this certainly describes someone who will certainly
contribute to pilot error. I dare say, those who are eminently
familiar with how a standing wave works, or the math, use modelers.
Those who don't know how a standing wave works, or the math, are
rather flat-footed.

>I'm sure it was a boon for you when the slide rule was
>replaced by the electronic calculator, leaving your mind free from having to

Fortunately, I don't pursue issues that don't survive a simple
rationality check. This can even eclipse the need of a slide rule
with a few figures sketch on a paper, and some simple computations.

>If you make a
>stupid mistake, don't fret, somebody will correct the parameters and re-run

Ah, but the introduction of this last quote is significant: the
mistake is caught. One needn't be a conductor to enjoy music. On the
other hand, a conductor is eminently qualified (if one can use the
word) to enjoy music.

>What's missing with this, of course, is the part your grey matter is
>supposed to do. Grey matter can take a permenent vacation.

Again, you have already revealed a thought process of recognizing a
mistake. Stupid or otherwise is merely a value to the problem, not to
the process of obtaining the solution.

>I see no problem using a NEC to confirm a calculation or concept. But you
>seem to advocate its exclusive use as the only authoritative, indeed,

I am still waiting for you to reveal something that does it better.
Simply throwing brain cells at it hasn't offered us much product here
- except when the internal logic of some proclamation fails on the
starting blocks.

>Of course, I disagree and think that rraa still has room for real math and

A long and winding road, that. But cursing at air traffic because it
gets others there faster doesn't make blisters on your feet ennobling,
especially when you are as likely to arrive at the wrong destination
as any air traveler.

Answer why Maxwells laws must have a proviso added when they are considered LAWS
nOT theory but law When you jump the traffic lights you have broken the law.
Maybe your exception has a good reason but by its very use you have invalidated the laws that you are seeking to abide by.This does not mean that the program does not reproduce actual antennas because numourous modifications to make sure that it does. Doing this is tantamount to saying that Maxwells laws need the help of experts such as your self. Seems like a good job is being done but it doesn't change the facts. You have taken the lead offered by Maxwell but have reserved the right to modify these laws to obtain a better computor model.
Why was this deviation added when the discharge of a capacitor is in no way sino-soidal?
Same goes for a inductor. Explain your deviation from the laws of Maxwell!
As a computor programmer you never gave credence to other antenna programs that produced tipped radiators for maximum gain for the polararisation required? You stayed quiet to protect the sales of your own program and thus by your silence allowed true facts to be distorted on this newsgroup. There were many opportunities for you to say that Eznec confirmed this finding
but you said nothing, which in itself is a insult to ham radio. You modified Maxwell's laws and that is prohibited in mathematics if one is to follow a mathematical law which you then invalidate.
Nothing personal intended, just a statement of facts as I see them. I will accept factual changes if you deign to point them out in detail so they can be confirmed or denied.

Hi Stewart

Are you providing a *pair* of relatively large wires from the battery, one
for plus and one for minus?
This is like a puzzle and it is interesting to follow this thread. I
consider it impractical, but it would be interesting to learn if a small,
sealed lead acid battery located close to the phone lowers the "noise"
(after the pair if +/- is also installed).

If this was my project, I'd test the phone line quality with a test
antenna thats *not* grounded. That way I could be more confident that the
"noise" will be acceptable with some ungrounded antenna.

Oh darnit! Here I went and built several antennas designed with Eznec,
and they have worked just like the program said they would.

I guess I'll have to take the remaining ones down, since I was only
supposed to discuss them, not actually make and use them. Thanks for the
correction!

That's not true unless you consider Eugene Hecht to be misguided. He said standing waves are so different from traveling waves that they probably shouldn't even be considered to be waves at all since they are not even moving. Standing waves could hardly be any different from traveling waves and tend to create strange illusions in human brains. I have plotted the envelopes of the waves at http://www.w5dxp.com/TravStnd.gif Those waveforms could hardly be any different yet you asserted that they are linked by a trig identity.

A standing wave is not only different from an EM traveling wave, it cannot correctly even be called an EM wave because it is not moving at the speed of light in the medium, a technical requirement for EM waves.

I have asked you to prove your assertion that, using your trig identity, cos(kx-wt) = cos(kx)+cos(wt). Where is that proof?

> ... you almost inevitably end up lying ...

Misunderstanding you and repeating it back to you is not lying. Neither are my personal opinions proof of lying. I joke a lot but lying is against my ethics and religion. Being called a liar by liar is unacceptable proof. Would it be too much to ask to post one of my alleged lies instead of hoping that your handwaving and implications will accomplish that underhanded trick.

P.S. I'm on my daughter's computer posting from Google.

Art, please think about what you are saying.

The wavelength of 20 MHz is 70 ft. The wavelength of 60 Hz is
16,400,000 feet (3100 miles).

There is a power factor correcting capacitor every city block or so on
the 60 Hz system, i.e. approximately every 0.00003 wavelength. Are
there any power factor correcting capacitors hanging on a 20m dipole?
If the standing wave power factor was corrected on a 20m dipole, the
standing waves would disappear just like they do on the power wires.
Correcting the power factor on a standing wave dipole antenna would
turn it into a traveling wave antenna and there would be no
reflections from the end of the dipole. Our 50/60 Hz power
distribution systems are overwhelmingly traveling wave systems. The
power companies simply don't allow reflections to exist because they
don't get paid for reflected energy and they sure don't want it coming
back to the generator.

If you had a 60Hz generator feeding a low-loss 3100 mile open-
circuited transmission line, you would certainly observe a forward
wave, reflected wave, and standing wave all obeying the distributed
network reflection model rules.

Cecil,

I showed you exactly how the energy in a standing wave travels at the speed of light. Did you miss that message, or are you just pretending it didn't happen?

Neither you nor your buddy Hecht are likely to overturn more than 100 years of successful use of standing waves.

You wasted your time, Richard. Everyone should already know that there
are received reflected waves of all different frequencies on a
traveling wave antenna. However, they can all be completely ignored
since we are only interested in the one frequency on which we are
transmitting *and* in the direction to which we are transmitting.
Introducing all the other extraneous frequencies and directions that
exist is an act of desperation.

In particular, we are not interested in the received standing waves
that are incident upon our terminated rhombic when they are coming
from the side or back of the antenna. That they exist proves
absolutely nothing of value.

I don't think I missed it, Gene, but it is possible. There is no net energy movement in a standing wave because the forward Poynting vector, Pz+, and reverse Poynting vector, Pz-, are equal magnitude and opposite directions. Therefore, no net energy movement is possible in a standing wave.

In contrast to that standing wave, there is always net energy movement in a traveling wave. If you can prove net energy movement in a standing wave, you will have violated the definition of a standing wave.

Of course it's true, and Dr. Hecht does post here.

> He

On what page has Dr. Hecht written "a standing wave is a different
kind of electromagnetic wave"?

> Those waveforms could hardly be any different yet you asserted that
> they are linked by a trig identity.

I asserted that expression for the sum of traveling waves and the
expression for the resulting standing wave pattern are related by trig
identity, as per page 140 of the 28th Edition of the CRC Standard
Mathematical Tables Handbook.

> A standing wave is not only different from an EM traveling wave, it
> cannot correctly even be called an EM wave because it is not moving at

The 'wave' which stands is merely an amplitude envelope for the waves
which move. It's not a "different kind of electromagnetic wave." If
you were to instead characterize a 'standing wave' as a different kind
of interference pattern, then we would in fact be in agreement.

Hi Dan,

I want you to take this quote above and observe that it offers nothing of data, and certainly says nothing of any model (except by the slightest of inference), and there is nothing of a practical measurement.

It does touch on the gray matter you aspire to keep active in the game, but only to recite homilies that do not attend the discussion. One could as easily demand that Ohm's law describes conduction, but say nothing about current, voltage, or resistance. Yes, all very true about Ohm, but hardly dismissive of prior models presented or their data that they deliver (by whatever means), nor how the sum of these typical engineering considerations fails to conform to the logic of Cecil's proposed argument.

By the points:
!. different frequencies is not an issue, only one has ever been expressed;
2. direction is not an issue, excitation is by degree only, nothing changes the energy distribution in relative phases nor period;
3. termination was not my issue (although I conformed to Cecil's demand that it should be) as I had already accounted for it;

4. they (Standing Waves) exist may be nothing of value, but only for a desperate celebrity who discounts his argument, impeaches his models and disinherits their data.

If you still find EZNEC a poor mechanism to support an argument through its means of presenting what you might call suspect data, then the quoted response to my posting above, has to be light years further from a rational conclusive demonstration. ;-)

So do we now have a new requirement for waves and photons that there must be *net* energy flow? Who cares what the average or *net* is. Think *instantaneous* if you want to understand photons. After all, they don't stand still, and they don't interact with each other.

You claimed that standing waves cannot be real waves because they cannot obey photon rules. I easily demonstrated that idea is incorrect.

The message was sent on January 3, at 4:32 pm, in the thread "Re: Standing-Wave Current vs Traveling-Wave Current".

Cecil,

That is an interesting tale, but mostly baloney.

When you get back to the wilds of Texas go check out some rural power lines. Count the number of power factor correcting capacitors you see. I bet it is a lot less than the equivalent of one per city block. Power factor correcting capacitors are intended to correct for reactive loads, such as motors, not for reflections or standing waves on open ended power transmission lines.

But you already know that.

This is what is done on a near-field antenna range. For certain
scanning geometries, the math is fairly straightforward (e.g. Fourier
transforms). For others, it gets complex, especially if the scanning
points are not evenly spaced.

A further complication is that you need to make 3 axis measurements of
both E and H.

Cecil:

Break down and buy a laptop (even a used one.) Make sure it has a wireless card or, get a USB wireless dongle (make sure the laptop has USB ports!)

Jiwire(http://www.jiwire.com) can be used to find any free wireless hotspots in the areas you are in, or even paid ones--for that matter.

Without you, it's too boring ... Sometimes this is better than an Indiana Jones movie! You know, the type of movies where the natives want his head on a stick. <LOL>

Warm regards,
JS

The challenge is that one needs a probe that measures 3 axis E and H. There are some clever designs out there based on a sphere with 6 half loops sticking out. They've been used to make near field measurements of broadcast stations, among other things. See, for instance, Gassman and Furrer, 1993. Silva, et al., published an interesting fiber optic probe scheme in 97. Driver and Kanda published a optically linked sensor for making Poynting vector measurements in the near field in 1988 (IEEE Trans EMC). In the microwave area, the probe is usually an open ended section of waveguide.

There are some clever techniques (see, for instance, the work of Bolomey) where you put an array of small (non resonant) dipoles with switches in the near field, and turn them on and off. You look at the antenna's feedpoint impedance and from that, you can tell what part of the field is affected by that dipole.

Once you've got your near field data, you need to post process. A gentleman, A.C. Newell, literally wrote the book(s) on this technique at NIST/NBS.

But you may have a problem discussing on the ng exactly "why" they
work. Why would you want to discuss an antenna if you don't care "how"
it works, you only care "that" it works? There are some people that
operate at 27MHz who don't care how their radios work, only that they
can peg your meter at 10 pounds.

Semantics. The standing wave doesn't 'travel' anywhere, much less at
the speed of light. However, it does vibrate. Each vibration cycle
occurs at a frequency that, when multiplied by its wavelength, would
be equal to the speed of light. I find this an interesting concept.

Roger Sparks wrote:

> Using the reflection point as the zero reference seems to correspond with an observation you made about the end of the line controlling the SWR.

The choice of zero reference is entirely arbitrary; any point on the line, or off the line, for that matter, can be used. I used the input end of the line as the x = 0 reference, so my equations are correct only when that reference is used. The choice of a reference has no effect on the SWR or any other aspect of line operation; it simply modifies the equations.

For example, my equations for the first forward and first reflected voltage wave were:

vf1(t, x) = sin(wt - x)
vr1(t, x) = Gl * sin(wt + x)

and for the second set:

vf2(t, x) = Gs * sin(wt - x)
vr2(t, x) = Gs * Gl * sin(wt + x)

where here I've explicitly shown the source and load reflection coefficients as Gs and Gl respectively. They were 0.5 and 1 in my second analysis (the one with a 150 ohm resistor at the source).

The more general case where the line is some length L, rather than the integral number of wavelengths in the example,

vf1(t, x) = sin(wt - x)
vr1(t, x) = Gl * sin(wt + x - 2L)

vf2(t, x) = Gs * Gl * sin(wt - x - 2L)
vr2(t, x) = Gs * Gl^2 * sin(wt + x - 4L)

In general,

(1) vfn(t, x) = (Gs * Gl)^n * sin(wt - x - 2nL)
(2) vrn(t, x) = Gl * (Gs * Gl)^n * sin(wt + x - (2n + 1)L)

where L is expressed in the same units as x and wt (degrees or radians).

These equations are correct with x being the distance from the input end of the line.

You could, as I mentioned, use a different reference, for example x' = L - x, where L is the line length in radians or degrees (same units as x and wt). Then you have, simply by substituting L - x' for x:

vf1(t, x') = sin(wt - L + x')
vr1(t, x') = sin(wt + L - x' - 2L) = sin(wt - L - x')

and so forth, and for the general case,

(3) vfn(t, x') = (Gs * Gl)^n * sin(wt + x' - (2n + 1) * L)
(4) vrn(t, x') = (Gs * Gl)^n * sin(wt - x' - 2nL)

or, you can use x for the forward wave and x' for the reverse wave or vice-versa in order to reference to the point the wave was reflected from or where it will be reflected from. Any combination of the equations is equally valid and will give correct results. You can't, however, simply redefine the reference point without a corresponding change in the equation. In general, equation 1 and equation 3 will give different results if you put in the same value for x and x'; likewise equations 2 and 4. There are some special cases, as you showed, where you can change the reference without modifying the equations and not have any impact on the sum of the waves. However, you can see from the equations that this won't usually work.

The general case with complex reflection coefficients and arbitrary line length is mathematically a little more difficult than the simple example I worked earlier. Not only does each reflection have a different amplitude than the previous one, it also has a different phase angle, due to the line length and the reflection coefficients. Consequently, the simple a / (1 - r) formula I used for summing the infinite series of waves can't be applied to the equations in the form I used. This is where a change to phasor notation is really beneficial, since the phase delay simply becomes e raised to an imaginary exponent which can be treated more conveniently than its constituent sine and cosine functions. With phasor notation, the summing formula can be used even for the general case to find the steady state results from the individual reflected waves. There's a very excellent treatment of this in Chipman's _Transmission Lines_ (Schaum's Outline Series). He does just about exactly what I did in my earlier posting, except for the general case and using phasors rather than time representations. It's an excellent text and reference, and I highly recommend it for anyone seriously interested in transmission lines.

Art wrote:
"Yes 50/60 is frequency just like 10 meters."

What is wrong with that statement?

The frequency corresponding to 10 meters is 30 million cycles per second. The wavelength corresponding to 50 Hz is 6 million meters.

A point a few meters from another along a 50 Hz line must have the same voltage as that of the other point on the line a few meters away because the 50 Hz wave changes its value so slowly as compared with wave velocity, about 300 million meters per second.

At the same distance between points on a 30 MHz line, the voltages of two points are surely different at the same instant because the wave changes its value rapidly.

Cut a line carying HF of 30 MHz and the voltage doubles at the open circuit while the current is completely reflected, making a sum of zero amperes at the cut.

Best regards, Richard Harrison, KB5WZI

I don't think so. If he comes directly off the bat, there is no filter
system that he can construct that would equal the capacitance of the battery
for effectivity.

I disagree. There is no better filter for alternator noise than the battery.
If more people realized this, they sure would sell a lot less filters. All
filters also have series resistance. What do you mean by filter efficiency?
The amount of noise turned into heat? How hot does a battery get from
alternator noise?

Thank you for responding Cecil as well as not being abusive.
Still looking at the first statement as I cannot move on without
closure.
Your point about a antenna having a open circuit at the top is a
troubling point for me.
For a given frequency the wave travells a certain distance forward and
the a certain distance back.What you are saying is if the antenna is
short then the wave or current flow will always about turn.
Thus it is the length of the antenna by your statement is what turns
around the current

regardless of the frequency applied. Thus if I reduced the antenna to 1 inch length the current will turn around multiple times by the time that a period for say 10 metres has expired.
Since the current supplied travels on the outside of the antenna it will be radiating all the time (as I understand what you are saying) without pulsating . I suppose you can prove this being a electrical person! For me it is the time that the antenna is actually radiating for a given frequency that is important so perhaps you will kindly relate travel distance, time taken
with the period duration of the frequency applied? There will be efforts to change the subject under discussion which would make this one small point last a few years but I do think it is worth clarifying for all so a solid base can be built. I would appreciate it if you would clarify what sort of antenna we are referring to ie a full electrical wave or a half electrical wave (resonant or otherwise)so that I may relate to either a series circuit or a parallel circuit such that the discussion is neatly enclosed to prevent deviation.
Very Best Regards
Art Unwin

Corrections:

The equations I gave aren't adequate for complex reflection coefficients, which I didn't explicitly state. Also, I inadvertently omitted a multiplying factor in two equations.

The above equations are valid only for purely real reflection coefficients, as in the analysis I did.

> (1) vfn(t, x) = (Gs * Gl)^n * sin(wt - x - 2nL)
> (2) vrn(t, x) = Gl * (Gs * Gl)^n * sin(wt + x - (2n + 1)L)
>

For complex reflection coefficients,

vf1(t, x) = sin(wt - x)
vr1(t, x) = |Gl| * sin(wt + x - 2L + /_Gl)

vf2(t, x) = |Gs * Gl| * sin(wt - x - 2L + /_(Gs * Gl))
vr2(t, x) = |Gs * Gl^2| * sin(wt + x - 4L + /_(Gs * Gl^2)

In general,

(1) vfn(t, x) = |(Gs * Gl)^n| * sin(wt - x - 2nL + /_((Gs * Gl)^n))
(2) vrn(t, x) = |Gl * (Gs * Gl)^n| * sin(wt + x - (2n + 1)L + /_(Gl *
(Gs * Gl)^n)

where /_(qty) is the phase angle of qty.

> where L is expressed in the same units as x and wt (degrees or radians).
>
> These equations are correct with x being the distance from the input end
> of the line.
>
> You could, as I mentioned, use a different reference, for example x' = L
> - x, where L is the line length in radians or degrees (same units as x
> and wt). Then you have, simply by substituting L - x' for x:
>
> vf1(t, x') = sin(wt - L + x')
> vr1(t, x') = sin(wt + L - x' - 2L) = sin(wt - L - x')
>
> and so forth, and for the general case,
>
> (3) vfn(t, x') = (Gs * Gl)^n * sin(wt + x' - (2n + 1) * L)
> (4) vrn(t, x') = (Gs * Gl)^n * sin(wt - x' - 2nL)

A Gl term was inadvertently omitted from the equations for vr. With that
error corrected, and with complex reflection coefficients,

vf1(t, x') = sin(wt - L + x')
vr1(t, x') = |Gl| * sin(wt + L - x' - 2L + /_Gl) = sin(wt - L - x' +
/_Gl)

and so forth, and for the general case,

(3) vfn(t, x') = |(Gs * Gl)^n| * sin(wt + x' - (2n + 1) * L + /_((Gs
* Gl)^n)
(4) vrn(t, x') = |Gl * (Gs * Gl)^n| * sin(wt - x' - 2nL + /_(Gl + (Gs
+ Gl)^n))

The reflection coefficient phase terms are easily handled in phasor
analysis, in the same manner as the phase term related to the line length.

I agree the standing wave can be described as an "amplitude envelope" but it is also a real wave (that carries no power). If you consider the "superposition" of forward and reflected waves to be a new wave whose envelope is the resultant wave of the superposition, then I agree. The wave does not travel over distance but it vibrates such that its frequency, when multiplied by its wavelength, results in the speed of light.

But the wave travels nowhere.

Strange but true...;-)

Dear Jim Lux W6RMK:

I was not able to examine the probes that I saw in use at NBS in what was probably the mid-70s.

The probes that I did see and use comprised three, orthogonal, very short doublets with attached means for rectifying. The resulting DC was conveyed away through a resistive, plastic transmission-line crafted to be almost transparent to RF. These probes were used to estimate the size of strong EM signals in the vicinity of equipment so as to be able to put better numbers on EMC capabilities.

While one can make a reasonable estimate of field strength inside of a TEM cell (a big piece of transmission line) from external measurements, it is desirable to be able to estimate FS at spots inside of the cell. It is important to note that even with care, significant uncertainties remain in the estimates. All measurement comprise a minimum of two numbers: an estimate of the value and an estimate of the uncertainty of that estimate. You, and most on the group, know this, but it needs to be repeated.

Safety of life was involved with the testing then done. With the profusion of transmitters in close proximity of safety equipment today, it is a wonder that more lives are not lost with inappropriate actuations just within present cars. A reminder that the need for savvy RF engineers will not diminish, and sending that work off-shore to a low-bidder is dangerous and probably criminally negligent. The major US car makers, to pick an industry, expend a large, expensive effort to see that their cars are safe using resident engineers.

Warm regards, Mac N8TT

Richard added a good comment:

>When used as a filter, a battery is a capacitor with a series resistor.
"A very, very, very small resistor.

The practical matter of this, is that it is far easier and cheaper to
simply make the connection to see if it does the job, instead of
investing in a filter that might not work."

This was good, practical advice.

Someone else added that a dedicated ground wire direct from battery ground post to ground of transceiver could also help. More good advice.

Of course the goal of direct connection to the battery is to minimize series resistance which would raise the impedance of the battery filter, reducing it's effectiveness as a short circuit to alternator noise. After doing the very practical step of direct battery connection, the next step is additonal L-C filters on both power leads from battery to transceiver. Consider that the power leads are a transmission line for noise from alternator to transceiver.

A whole lot of people have gained a better understanding of why antennas work by using computer modeling. They observe how they work, discover it's not how they thought they worked, and are prodded into learning why they work. I've learned a great deal myself this way, and many conversations with EZNEC users over the years shows this to be a common benefit from modeling. It allows you to immediately see if your concepts are sound by showing you the results of their application. NEC and EZNEC don't design antennas; they only tell you how the antenna you've designed works. Chances are you won't design a very effective antenna if you have no idea why they work. People truly interested in learning more about why antennas work will arm themselves with as many available tools as possible.

A recent example of this philosophy was the transmission line analysis I recently posted. After working through all the math, which came from a basic understanding of transmission line analysis, I simulated the line with SPICE to confirm that my analysis was correct. Had it shown something different, I would have gone back to the math, or the model, or my basic view of transmission line operation, to resolve the discrepancy.

Arguments against using computer programs for antenna analysis are about the same as those against using a calculator to perform arithmetic. No, on second thought, more like arguing against using a computer to solve

systems of differential equations.

But, each to his own.

You can see graphically exactly where the energy and power are at every point along the line at every instant, with the program I made for the purpose. It even separately shows the energy stored in the E and H fields. See the recent TLVis1 thread.

While a car battery might have a reasonably low terminal-to-terminal impedance at RF (or might not - I don't have any direct experience, and think it's entirely possible it's not that good), the wire from the negative terminal to the chassis is typically on the order of a quarter wavelength at 2 meters. Even at lower frequencies, it can have considerable (inductive) impedance. So there can be a lot of RF between the battery and chassis. A car's ignition line, which connects to the battery, often has spikes of tens of volts or more, ringing at hundreds of kHz or less, relative to the chassis -- enough that the design of electronics which can survive in that environment is a challenging discipline.

> crossing the node, but its energy does not.

Take a look at demo 4 with the TLVis1 program (described in the TLVis1 thread). Let it run to steady state, then single step. In the upper trace, look at one of the points where the power is always zero, i.e., where it crosses the center line. But as you step, you can see that the energy at that point increases and decreases with time. In fact, at some times it's zero and at other times it's one of the points of maximum energy density along the line. So how can this be? The power is always zero at that point, yet the energy is increasing and decreasing with time.

The answer is that equal amounts of energy are moving to the right and left of that point at all times; energy is flowing into and out of that point equally from both sides. So although there are points where the power is always zero, those aren't the points where the energy isn't moving.

There are, in fact, points along the line where the energy doesn't change with time, but they coincide with the points where the power is maximum. This simply means that, at those points, however much energy flows into a point flows out at any given time, leaving the total energy at those points constant. (Mathematically, this amounts to the existence of a constant when you integrate power to get energy.)

So at all points along the open circuited line and at all times, energy is either moving, increasing, or decreasing. There aren't any static spots at all.

I find it very helpful to look at this visually -- that's why I wrote the program. It also shows how misleading it is to mix power and energy.

> Some readers like to superpose energy just as
> they do voltage, but in general this is not a
> valid operation so I am uncomfortable using
> it as the explanation.

I agree, you can't assign energy or power to the traveling waves separately and superpose them as you do voltage and current. TLVis1 calculates power and energy from the total voltage and current.

Come to think of it, there was a question in the extra class pool that deals
with this:

E4D05

Q. How can conducted and radiated noise caused by an automotive alternator
be suppressed?

A. By connecting the radio power leads directly to the battery and by
installing coaxial capacitors in the alternator leads.

> So do we now have a new requirement for waves and photons that there
> must be *net* energy flow?

It's not a new requirement, Gene, just a very old requirement of physics. Photonic, i.e. EM waves, do not flow back and forth as you are implying. As long as the medium is homogeneous, i.e. doesn't change, a photon travels at the speed of light in one direction in a medium. So yes, net energy flow is absolutely a requirement for photons.

EM waves *are* photons and do not vibrate back and forth in a medium. They travel in one direction at the speed of light in the medium until they encounter an impedance discontinuity. Virtually any physics book with a diagram of the EM wave E-field and H-field will show the direction of travel as one direction without the "one step forward and one step back" concept that you are proposing.

> You claimed that standing waves cannot be real waves because they cannot
> obey photon rules. I easily demonstrated that idea is incorrect.v

All you demonstrated was your ignorance of the nature of photons. Your analysis was incorrect. You are seeing the standing wave illusion and assuming an impossibility of physics. It is very clear that you and others simply do not understand the nature and physics of photons and photonic waves.

My gawd man, you are paying attention.

My question would be, with the constitution guaranteeing us the rights
to bear arms against a government which has become insensitive to the
majority--when will we finally find it intolerable and correct "them."
Or, when the common man has to think of the government as a "separate
entity" to the population--it is time for serious correction ...

Amen brother, it IS criminal!

Warm regards,
JS

Since I didn't say that Dr. Hecht said that, it must be a rhetorical question. Here's what Dr. Hecht did say: In "Schaum`s College Physics Outline" by Bueche & Hecht on page 214 is written: "Standing Waves:....These might better not be called waves at all since they do not transport energy and momentum." (Thanks to Richard Harrison for that quote.) I agree with Dr. Hecht. Standing waves should not be called waves at all since they do not meet the definition and requirements for EM waves.

> I asserted that expression for the sum of traveling waves and the

> Mathematical Tables Handbook.

Sorry Jim, that's not what you said. You asked if I recognized the trig identity that (presumably) equated a standing wave to a traveling wave. If that was not your meaning, it is time to say exactly what meaning I was supposed to assume.

> The 'wave' which stands is merely an amplitude envelope for the waves
> which move.

Key word there is "waves". A standing wave is NOT self sufficient - it requires the superposition of a forward-traveling wave and a reverse-traveling wave. A standing wave loses its EM wave identity in the process of that superposition and apparently creates an illusion capable of mass hysteria. To alleviate that hysteria, one has only to compare the equations for standing waves and traveling waves or the corresponding graphs of those functions to see that they are hardly anything alike.

My sisters' son has drawn some nice pictures on his bedroom wall with crayons--I can actually appreciate them--especially for his age--he does show some "artistic" leanings, in my humble opinion ... of course, I don't have to clean the crayon off the wall.

I am sure your endeavors, at least, should enjoy such observations/considerations ... :-D

> power transmission lines.

Within the city limits of my home town of Madisonville, TX, there is
approximately one capacitor every city block. I had one in my front
yard. But the exact number and distances do not matter one iota. Those
capacitors exist to neutralize the inductive reactance in the system
at the load. I use exactly the same method to twist the feedpoint
impedance of my 75m Bugcatcher to 50 ohms.

You said: "Power factor correcting capacitors are intended to correct
for reactive loads,"

:-) Reactive loads cause reflections. The opposite reactance reduces
reflections. Does that scheme of matching a transmission line to a
load sound familiar? :-) My Bugcatcher antenna has about 25=j25 ohm
feedpoint impedance on 40m. I install a -j50 cap from antenna to
ground to achieve 50+j0 at the feedpoint. That's exactly what the
power company capacitors do.

Reflections *ARE* power factor problems. When the power company brings
the power factor to unity, they have eliminated reflections and turned
the system into a traveling wave energy delivery system. That you do
not recognize the similarity between VARS and standing waves is really
strange indeed. Standing waves contain nothing except VARS.

OK. Let me go further then. If I were to allow "speculation" on the
existence of the ether--than I could further expand this "speculation"
to allow for a "lag" in the ether--and "to" that of the spinning
magnetic fields--and, if such "speculation" were allowed, then going one
step further would allow for the possibility of the "deformation" of the
"wave" thus generated by such a "lag" ...

The feedpoint impedance of these standing wave antennas can be closely
approximated by

Zfp = (Vfor+Vref)/(Ifor+Iref)

where all values are phasors. For instance, the reflected voltage will
be out of phase with the forward voltage at the feedpoint for a
resonant 1/2WL dipole while the reflected current will be in phase
with the forward current. The feedpoint impedance of a 1/2WL dipole is
very close to (|Vfor|-|Vref|)/(|Ifor|+|Iref|). See if you can figure
it out for other lengths of dipoles.

More accurately, I should say

...(the standing wave is a)...real wave (that carries no REAL power. It does contain REACTIVE power, which was called "imaginary power" at the University of Wisconsin, measured in VA's, not watts.

The standing wave current is 90 degrees out of phase with the standing wave voltage, thus energy (power X time) IS STORED in a standing wave but NEVER transmitted by the standing wave.

However, in a standing wave antenna (a lossy resonant system) the power contained in a standing wave will ultimately be dissipated by the radiation resistance and ohmic resistance, where the current and voltage stored in the standing wave are converted to REAL power as a traveling wave. With no ohmic or radiation resistance losses as in a perfect superconductor with no path to free space, the standing wave would simply oscillate forever with zero power applied at the feedpoint.

Just what is a "wave", anyway? Are there different "kinds" of electromagnetic wave? If so, what are they? Does a "wave" have to travel in order to be a "wave", or can it just "vibrate" or "oscillate"? Or just "stand"?

Most of my references call a standing wave a "pattern". Is a "pattern" a "wave"? Can a "wave" be a "pattern"?

That should be good for another few hundred posts, at least. Sheesh.

Roy,

The standing wave is the mathematical sum of the forward and reflected waves. This sum is a superposition wave. The components of the superposition wave no longer exist by themselves; they form part of the summation which is the non-traveling "standing wave". Like its forward and reverse components (each containing "real" power) that would have been traveling waves prior to superposition, and which have now ceased to exist, the summation wave is also a real wave that vibrates at a frequency that, when multiplied by its wavelength, equals c (but traveling nowhere), and stored with "imaginary" or "reactive" power, where the real power components have been changed to reactive power components. Energy is conserved. The real energy in the traveling waves has been changed temporarily to potential or reactive VA (Cecil calls it VAR....same thing) energy until it dissipates into the radiation resitance by the radiation of photons/waves through free space (ignoring ohmic losses which also dissipate real power). After dissipation of each photon or wave into free space (where E=hf, take your pick) from the theoretical radiation resistor, the generator (transmitter) source must replenish energy into the antenna to keep the standing wave stored-energy system oscillating and then depleting into radiation. Without constant replenishment from the generator, the standing wave diminishes to zero.

It is like an inductor, capacitor and radiation "resistor", all connected in parallel, and whose impedance is the radiation resistance of the antenna, which itself is related to the impedance of free space and the geometry of the antenna (as you know). What is not intuitive is where the other terminal of the "radiation resistor" is connected. But that is indeed where the traveling wave from the dissipated standing wave 'travels' to. That is where I find Art's material interesting. I do not think I have ever seen a depiction of this phenomenon that can be conceptualized but I think Art is trying.

OK, go ahead. Lock, load and fire ;-)

Hi Stewart,

Then a likely problem is in the audio side where it is supposed to be
floating, perhaps the lack of an isolation capacitor from a dual
supply amp that is working with a single supply (you can do this by
floating the ground return, as long as another ground isn't mixed in).
Basically, the audio ground is lifted to 6 volts and the audio swings
to either side of this, instead of +/- around zero.

Does your set come with an external speaker? If so, measure both
sides to ground (without the coax grounded, of course).

Hi STW.
Been There Done that!!!
Yes OM we've tried all sorts of search receivers and antennas. Had some success in locating some vey poorly maitained insulators in a 32Kv overhead line about 500 metres from our 2 QTH's. Problem is the liabilty for interfernce is very poorly defined here in NZ. The power generating companies and line companies are separate and poorly coordinated as a result of abortive privatisation in the 1980's an 90's.
We have our people from our Trade and Industry dept involved already. These are the equivalent of our Radio Inspectors of earlier times and are of some help.
However we are now both concerned that the interference may be carried or even caused by faulty earthing arrangements in our local underground "neutral earthed" system. I am a registered electrician and my fellow Ham is actually employed by a lines company.
So much for my nice electrically quiet section on a hilltop for my retirement!!!
However I will follow up some of the pointers which have been suggested and hope that now the main summer holidays are coming to an end down here some maintenance work will get done.

Hi Stewart

Is it practical to *open the braid* of the coax? I wonder if it is
practical to cut the outer conductor of the coax and solder a 1/4 wave stub
across the gap.

Jerry

Non sequitar here?

I do care about why and how the antenna works. I just don't agree with AI4QJ's premise that Eznec is for discussion purposes only. It isn't, it works just fine for design and implementation of them also.

Its a good tool for design of antennas. It gives me the data I need and the expected outcome. I've designed simple antennas using "personal level math" too. I don't do that much any more. I did the calculations on paper too. I don't know if that makes them better than if they were done using a calculator though.

I really don't want to be involved, the complexities of this argument
are too great a demand for my time, and I lack the deep understanding to
add beyond where others have already gone (indeed, they have gone well
beyond my understandings--I play a game of catch-up.)

However, I don't believe anyone is actually dismissing EZNEC. I know of
no better which does what EZNEC does. Nor am I aware of anyone actually
attacking the personalities behind or around EZNEC--it is the premises,
formulas, equations EZNEC is based on which harbors the discussion ...
and such discussion cannot hurt.

I believe the above is most accurate--just now and then a temper might
flare ...

You never give up, do you? Even when you are caught in an utter lie. You know exactly what the capacitors are for, and it isn't to control transmission line reflections from open ends of the line.

I do know it has been speculated that events on the sun have caused "phenomenon" in utility lines to the point of power outages. Indeed, I think there is still some mystery about why this occurs. And, I know power companies have tried some fixes to these ... decades ago I had line noise to the point I contacted the power company. They sent someone out and, I thought, installed some sort of cap/filter on the line--anyway, they did "stick something up there you could see." I did notice a slight improvement--but finally ended up giving up the battle with them ... a move to a quieter location changed everything.

Regards,
JS

And so do I. But as I said, I am not disputing anything that Dr. Hecht has written in his textbooks. Though, there are more elegantly written physics books.

Should we add an L to vf1(t, x, L) to keep the notation consistant in that we are considering 3 phase components. Rewriting,
vf1(t, x, L) = sin(wt - x + 0*L) (input point is congruent with refection point)
vr1(t, x, L) = Gl * sin(wt + x - 2L)(2L evaluates the entire line travel time)

I get your drift here. You are writting the general equation as if the first event is event zero, computer programming style.

Shouldn't these be written like this, changing the term "(2n + 1)L"?

(1) vfn(t, x) = (Gs * Gl)^n * sin(wt - x - 2nL)
(2) vrn(t, x) = Gl * (Gs * Gl)^n * sin(wt + x - 2(n+1)L)

A14QJ wrote, quoting Roy:
"Just what is a "wave", anyway?"

Wikipedia says:
"Waves travel and transport energy from one point to another, often with no permanent displacement (mass transport) of particles in the medium; instead there are oscillations around almost fixed positions. A traveling wave varies with both time and distance. Phase velocity=Lambda(f).
A standing wave remains in a constant position and only may be the result of interference between two waves traveling in opposite directions

When two opposed waves cancel, there is no net propagation of energy."

The "Hutchin Encyclopedia" says:
"Nodes (positions of zero vibration) and antinodes (Positions of maximum vibration) do not move.

Water and EM waves can form standing waves in the same way."

A14QJ also wrote:
"The standing wave is the mathematical sum of forward and reflected waves. This sum is a superposition wave. The components of the superposition wave no lonnger exist by themselves;----"

The components are not cancelled. Were that so, the Bird Thruline Wattmeter could not function and the standing wave would be independent of the forward and reflected waves. Instead, it is only a manifestation of interference.

Best regards, Richard Harrison, KB5WZI

Yes.. The older works (50s and 60s) used carbon loaded string or
thread, but newer stuff uses conductive plastic. If the sheet
resistance of the material is 377 ohms/square then it's sort of like
lossy freespace.

Those three axis probes work fine for measuring the magnitude and
direction of the field, but they can't measure the phase, and to do
the nearfield to far field conversion you also need the phase.

Art wrote:
"This dust is what Gauss refers to as static particles in a
gravitational field in equilibrium."

What evidence do you have that gravity is related to static particles
other than attracting their mass or that gravity affects radio waves
significantly?

Our universe may not have uniform acceleration, so are you sure about
equilibrium?

Maxwell did not need a medium for radio propagation. He was able to
calculate the velocity of radio waves and believed that because it
equaled the known speed of light his equations were correct.

Take a look at the E-field, H-field, and direction of travel for an EM (photonic) wave. An RF standing wave does not behave like an EM wave nor does it meet the definition of an EM wave which can be represented by a Poynting vector. The Poynting vector for an RF standing wave has a magnitude of zero and no direction.

Yes, that's fine. It can be viewed as either a variable or a constant, but it won't change during the course of a single analysis.

> vf1(t, x, L) = sin(wt - x + 0*L) (input point is congruent with refection point)

It's not necessary to explicitly add the 0*L term, even if you consider vf to be a function of a variable L. And it adds unnecessary clutter and potential confusion without any effect on the result.

> vr1(t, x, L) = Gl * sin(wt + x - 2L)(2L evaluates the entire line travel time)

The equation is correct and what I wrote. I don't understand the parenthetical comment.

>> In general,
>>
>> (1) vfn(t, x) = (Gs * Gl)^n * sin(wt - x - 2nL)
>> (2) vrn(t, x) = Gl * (Gs * Gl)^n * sin(wt + x - (2n + 1)L)

>
> I get your drift here. You are writting the general equation as if the first event is event zero, computer programming style.

Sorry, I don't know what event you're talking about. And it's not "computer programming style", but standard notation as you'll find in any text. I am making the assumption that the line is initially discharged, if that's what you mean.

> Shouldn't these be written like this, changing the term "(2n + 1)L"?
>
> (1) vfn(t, x) = (Gs * Gl)^n * sin(wt - x - 2nL)

>

You're right. I made an error -- thanks for spotting it. The reflected
wave has an additional 2L delay relative to the corresponding forward
wave, and I didn't write it correctly. I apologize for the error.

>> You could, as I mentioned, use a different reference, for example x' = L

It depends on your ability to visualize equations, which usually
improves as you work with them. But sketches of the waves are definitely
very helpful in keeping track of what's going on. I hope my little
program will also prove helpful for this.

> This has been very productive for me Roy. I am gaining a much better appreciation for the
whole subject, especially the use of phasors. Your use of the phase angle (posted with the

>
> Thanks for your efforts.

You're welcome. I'm glad to help when I can. Chipman's book might be
hard to find, but it's well worth the search. I have more than a dozen
texts dealing with transmission lines, but Chipman's has material, like

the concise development of steady state from startup, that you'll find in few others.

I haven't used phasors in these postings at all, but would have to in order to sum the waves for the general case. In phasor notation,

vfn(t, x) = (Gs * Gl)^n * exp(j(-x - 2nL))
vrn(t, x) = Gl * (Gs * Gl)^n * exp(j(x - 2(n + 1)L))

where Gs and Gl are complex. So the ratio of successive terms vfn(t, x) / vfn-1(t, x) = vrn(t, x) / vrn-1(t, x) is a multiplier term Gs * Gl * exp(-j2nL). So we can use the formula for summing an infinite series to get

vf(ss)(t, x) = vf1 / (1 - Gs * Gl * exp(-j2nL))
vr(ss)(t, x) = vr1 / (1 - Gs * Gl * exp(-j2nL))

which can be evaluated as complex numbers and converted back to time functions for evaluation. While the summation of the infinite series could almost certainly be done by clever application of trig identities, it's trivial with phasors.

High Mac,

About a year ago I was at an EMC test house. They were experimenting with three axis short dipoles with a detector diode in between. I never saw such a small package for a diode, maybe it was just the chip on top of the substrate.

The output goes via a high resistance metallic layer to the interface. The whole interface is fed by fiber optic (data also goes via fiber optic). It wasn't used for antenna design measurements but for EMC high field strength measurements. Their intention was to use it up to 18 GHz. Of course sensitivity (conversion from E-field to DC output) is very poor, but for high incident field that isn't a problem.

For indicative measurements I like today's easy to get medium barrier microwave schottky rectifiers (like BAT15 and BAT 62). Together with a CMOS input stage opamp one can make a nice zero bias detector with good temperature stability and that outputs the full available EMF from the rectifying diode. So you can calculate back the incident E-field.

Best regards,

Wim

A wave is any periodic function f(x) where f(x) = amplitude and whose
period X defines one cycle.

The first sentence says that waves travel. The second describes a wave
which doesn't. Which is it?

> When two opposed waves cancel, there is no net propagation of energy."

It's statements like that which make me very leery of Wikipedia.

That's fine and good. But it doesn't define what a wave is.

A Bruene wattmeter circuit measures "forward power" and "reverse power"
just fine simply by measuring the voltage and current at a single point
on the line. It doesn't measure separate forward and reverse waves, but
only the total V and I. Was Bruene more clever than Bird, who you say
can't figure out how to do that?

Well, there was the one person who started this exchange with a very sarcastic comment. I'm not sure who it was but this mystery person said:

"Oh darnit! Here I went and built several antennas designed with Eznec, and they have worked just like the program said they would.

I guess I'll have to take the remaining ones down, since I was only supposed to discuss them, not actually make and use them. Thanks for the correction!"

Unexpected and unnecessary sarcasm pointed in my direction tends to make me appear sanctimonious and to respond in kind.

Anyway,

The single pulse can be decribed by its fourier series a superposition of
sinudoidal waves so you would actually be sending wave(S) down the line, of
varying harmonic frequencies, but only for the time defined by the pulse
width.

So a sine wave consisting of only two cycles is considered a periodic function? How about one cycle? Half cycle? Does a truncated sine wave fit the proposed definition of f(x) where x is the period? Would the pulse then be one wave or an infinite number of waves (since the spectrum of any time-limited function is infinite in width)?

Wouldn't it be fun to calculate the power in each of the infinite number of sine waves and add them together like Cecil does to get the total power? Boy, I'll bet you'd have a *lot*!

Yes, for a time period of 2 cycles it is consuidered a periodic function.
When it is interrupted, it stops existing.

> How about one cycle?

Same as above.

> Half cycle?

Same as above.

>Does a truncated sine wave fit the proposed definition of f(x) where x is
>the period?

Yes, absolutely. So does a square wave, a sawtooth or any periodic wave.

> Would the pulse then be one wave or an infinite number of waves (since the
> spectrum of any time-limited function is infinite in width)?

Yes. It is possible that the pulse could be described, for example, as the
summation Capital Sigma [limit n =1 to infinity]{1/n**2*(cos(n*2*pi*f*t)}
which would be an infinite number of cosine waves whose amplitudes (and
energy) gradually approach zero in accordance with n**2.

>
> Wouldn't it be fun to calculate the power in each of the infinite number
> of sine waves

Periodic waves are typically in the above form or similar. Integrating the
"infinite" number of waves the above expression is trivial and results in a
finite number as long as time "t" is a finite number. It is normal to
integrate any periodic wave over a finite time period and get a finite
result, even if the fourier series indicates an infinite number of
sine/cosine waves. That's just calculus.

> and add them together like Cecil does to get the total power? Boy, I'll
> bet you'd have a *lot*!

I'm sorry but this taunt rings a little hollow...it just isn't funny because
you can/will get a finite number for power.

CORRECTION: Should be 'approach zero in accordance with 1/n**3' as that will
be how the term shows up when solving the integral.

I'm sorry, Gene, but I cannot alleviate your ignorance with one posting. Given a voltage phasor and a current phasor with a phase angle between them, there is absolutely no way to distinguish between a mismatch and a reflection. The purpose of those power factor capacitors on the power line poles is to turn those transmission lines into money-making traveling wave delivery systems rather than allow money-losing standing wave systems. Please stop your emoting long enough to realize what I have said is true.

If the capacitors were not there, the inductive loads would cause reflections just as they do on an RF transmission line. The only difference is that the 60 Hz transmission line is a small fraction of a wavelength. If you scaled the 60 Hz system to 6 MHz, all the same laws of physics would apply and the similarities would be readily apparent.

I don't remember saying that and I apologize if I ever did. What I
remember saying is that an RF standing wave doesn't meet the
definition of an EM wave which is essentially the same thing that Dr.
Hecht said: "Standing Waves:....These might better not be called waves
at all since they do not transport energy and momentum."

RF standing waves, unlike other EM waves, do not transport energy and
momentum at the speed of light in the medium. Therefore, they are
technically not EM (photonic) waves.

Exactly. With a high input resistance voltmeter at the far end, the net
resistance of the resistive line has little (and predictable) effect. What
I saw was not loaded string - it was a conductive plastic.

>
> Those three axis probes work fine for measuring the magnitude and

>

Exactly. I did not intend to leave a suggestion that the probes used to
estimate the size of strong EM fields could provide phase information. The
utility of the probes that I saw and used resided in their insensitivity to
the local polarization and their useful sensitivity to the magnitude of E.
The testing of such polarization sensitivity and the calibration of
magnitude of E is straight forward when one has a TEM cell, a power
amplifier, a calibrated high-power attenuator, and a trustworthy power

meter. Still, the results of EMC testing will have uncertainty.

Once upon a time, a major effort was made to estimate the strongest E to be found in the environment. Testing took place on SW broadcast sites and a host of other places. I ran a mobile test on a drive from the East Michigan area to Chicago. My testing found CB signals and VOR signals to be the strongest. The former because our van was passed by a car transmitting at 27 MHz and the latter because the (about) 200 watt VOR was at ground level, near the highway, and its antenna was surrounded by a very large ground-plane. Others found a particularly strong signal from an FM broadcast station with a mis-designed antenna having a major lobe straight down! Today, many more RF hazards exist. Thanks for your expansion of what I wrote. 73, Mac N8TT

If the wire runs in the 'x' direction, the standing wave phasors
rotate only in the 'yz' plane. Since the Poynting vector is always
normal to the E-field and H-field, seems the instantaneous value of
the Poynting vector for a standing wave is still zero.

Sorry, the dipole standing waves are only about 80% of the energy on
the antenna. The other 20% of the energy is radiated (or lost to
heat). If the waves on the 1/2WL dipole were 100% standing waves, the
antenna would have a zero feedpoint impedance, but it doesn't

You could shortcut the whole process and just have Dr. Hecht post his ideas here instead. I bet ya anything there would be far fewer arguments about physics. :-)

Technically, they're just spatial interference patterns, so of course they don't propagate energy. They're like any other spatial interference pattern in that regard.

Dear Wim: Your observations are appreciated. I am delighted to learn of evidence of improvements in instrumentation.

Along with my early observation of the need for capable RF engineers (and that includes antennas), note in the digital age the continuing need for smart analog-electronic engineers, as exhibited by your examples. Western Europe, USA, Canada, ZL, and VK still have such people, but many are reaching retirement. I am please to say that my university still has as one of its objectives to educate engineers who have a good feel for when analog is needed and when digital is needed. They might not have the full analog insight, skill, or experience, but they know when an analog expert is needed.

... and now for a moment with tongue-in-cheek: Too many words in English sound the same, but are spelled differently. Some are spelled the same but have multiple meanings that one must gather from context. This is the consequence of borrowing from many languages - very notably from the north part of your country. "Hi Mac" is a salutation. It should come as no surprise that this Mac has never been "High."
The most wonderful thing about English is that because of its inherent redundancies and the way it uses grammar, it is relatively difficult for anyone to loose the meaning - especially in a technical forum. As a contrast, consider the drastic consequences of making an error in an ending of a Slavic language word. The word can become unintelligible.

Your contributions are always read with interest. 73, Mac N8TT

A standing wave is an amplitude vs position envelope. An amplitude vs
time envelope is modulation! :-)

Thanks for offering the two capacitor/one capacitor view of the middle
of the line. It took a bit of time to decide whether the commingling
of the charge in the single capacitor at the middle of the line would
solve my dilemma.

So I considered this one capacitor in the exact center of a perfect
transmission line. It is the perfect capacitor, absolutely
symmetrical. So as the exactly equal currents flow into it on
the exactly symmetrical leads, the charge is perfectly balanced
so that the charge coming from each side exactly occupies its
side of the conductor. As the two flows of charge flow over
the perfectly symmetrical plates, they meet in the exact
center, and flow no more. I conclude that a surface can
be found exactly in the center of this capacitor across
which no charge flows. Thus (un)happily returning me exactly
to where I was before; there is a line across which no
charge, and hence no energy, flows.

More comments below.

I would really appreciate seeing some other possible explanations.

One other one which I have seen and am not confortable with is the explanation that energy in the waves pass through the point in each direction and sum to zero. But this is indistinguishable from superposing power which most agree is inappropriate. As well, this explanation means that P(t) is not equal to V(t) times I(t), something that I am quite reluctant to agree with.

The other explanation seen is that the voltage waves or the current waves travel down the line superpose, yielding a total voltage and current function at each point on the line which can be used to compute the power. With this explanation, P(t) is definitely equal to V(t) time I(t), which I do appreciate. The weakness of this explanation is that it seems to deny that the wave moves energy. And yet before the pulses collide it is easy to observe the energy moving in the line, and if a pulse was not coming in the other direction, there would be no dispute that the energy travelled to the end of the line and was absorbed in the load. Yet when the pulses collide, no energy crosses the middle of the line. Yet energy can be observed travelling in the line before and after the pulses collide.

So...

I can give up on pulses (or waves) moving energy. I am not happy doing that.
I can give up on P(t) = V(t) * I(t). I am not happy doing that either.

So the (poorly developped) "charge bouncing" explanation seems like a way out, but I certainly would appreciate other explanations for consideration.

> None of these make an argument with your logical development, although I

So I am not convinced that it any way goes against established theory. I have not seen established theory attempt an explanation of how the waves can both transport energy as well as not do so when waves of equal energy collide.

> can be made that it's not necessary at all. I suspect this is the case.

The same concern that arises for pulses of equal voltage also
occurs for pulses of different voltage. While the mid-point no
longer has zero current, the actual current is only the difference
of the two currents in the pulses, the charge that crosses is only
the difference in the charge between the two pulses, and the
power at the mid-point is exactly the power that is needed
to move the difference in the energy of the two pulses.

So the challenge is not so starkly obvious as it is when the
power at the mid-point is always 0, but P(t) = V(t) * I(t) can
still be computed and it will not be sufficient to allow
the energy in the two pulses to cross the mid-point (unless
one likes superposing power, in which case it will be
numerologically correct).

> beyond this.)

I sometimes think that this may actually be a debate about the
conceptual view of waves. If waves consist only of voltage and
current, then all is well, superposition works, the correct
answers are achieved. And if the power is computed after the
voltages and currents are arrived at, all is well.

But if one conceives waves as also including energy, then it
seems that the question 'where does the energy go' is valid
and the common explanations do not seem to hold up well.

Yes, indeed. Though any (new) explanation would have to remain
consistent with the existing body of knowledge which works so well.

I amnot sure how they came into the earths atmosphere but Gauss has
them placed in a field in equilibrium. I do not believe and I have
not said that earths gravity has any affect on propagation.
Remember, the static particles have a very weak anti gravity
force which nullifies the earths gravitational or magnetic forces.
Thus the static particles can take a straight line velocity.

>
> Our universe may not have uniform acceleration, so are you sure about
> equilibrium?

Yes I am. That is a basic for a Pointings vector and most certainly
for Gauss.
Both of these analysis are dependent on the gravitational field being
spherical
so the calculations have to be modified slightly because out earth is
lemon shape
but it is close enough for calculations

>
> Maxwell did not need a medium for radio propagation. He was able to
> calculate the velocity of radio waves and believed that because it
> equaled the known speed of light his equations were correct.

Well his equations are correct as are the laws that he condensed.
Lorenz law however was on the basis of deduction or observance
which turned out to be correct but there were no details for
Maxwell to hang on to which leaves all as a very difficult puzzle
I started the aproach of continuing Gausses work on static which
the books seem to relate as a subset of electro magnetics.
So I added a time varient to a static field which provided
a direct connection to Maxwells laws. Thus at this point I
accept the static particles at rest and inserted a radiator
in the field which ofcourse must be resonant and in equilibrium
so it didn't upset the Gaussian field. When this was done we
have a dynamic field from which we can draw the statement

that a radiator made from a diamagnetic material can be any
\hape, size elevation e.t.c as long as it is in equilibrium.
Thus this observation or deduction states that a helical
antenna is not in equilibrium unles the windings have
balancing contra windings. Thus any wound design such as EH
ntennas or Vincent antenna must have contra windings to be
in equilibrium and thus fully efficient.
Armed with the above I placed a radiator into a computor program
with an optimizer and confirmed the above i.e. it was not planar.
So why was the element tipped from parallel to the earths surface?
If you make a vector analysis of a radiator with it's many vectors
the resultant single vector is not parallel to the axis of the
radiator.
In addition I look at a helical design and not that the pitch angle is
the same
found by Kraus experimentally was the same angle as the resultant
vector of a radiator.
We then examine the radiator with a static particle at rest on it's
surface and then make a electri9cal circuit of what we see. The result
for equilibrium must be a tank circuit where
all enrgy is interchanged between the energy storage tanks(inductance
and capacitance)
Both of these expend there energy as if the terminals were shorted,
and who hasn't shorted a capacitor to generate an explosion.One can
imagine a explosive force sliding or lifting the static particles to
the inductor reciever which because the material is diamagnetic the
lines of force of the magnetic field will levitate or thrust the
particles away from the
radiator. Using Newtons law we can see that the reactionary force of
the ejected particles
will imping on the radiator itself ad make it occilated. Of course the
particles are many and the number of periods in the frequency applied
is like generating a horrendous number of samples of oscillation, much
more than the human ear does and these samplers will then apply
a mirror image of the occillationd to the recieving radiator.
So like a jigsaw puzzle the measure of difficulty in solving the given
problem is determined by the starting point. And tho I manipulated
Gauss to a Maxwell form which was the same masthematical law,as with
all things it is not only the destination that counts but everything
one observes on the way.
The bottom line is that for best efficiency for the unit volume
supplied an array must be in equilibrium. Thus distances between
radiators become smaller and elements which can be helically wound is
also shorter and by virtue of the array not being planar we have a
single feed plus the "stacked"gain.
I have not made an array but I have made many helical designs and the
like.Programs confirm
these as being legitamate. The fact that I modified the static law to
a dynamic law is the only thing that is "different". Every other
action along my travels are extensivly studied in the books tho not

relavent to radiation. I say again, the complexity depends on where
you start
and I did not view static as a subset like the books do.

This would not be quite correct. The power factor correction
capacitors make the load impedance real, they do not match
the load to the impedance of the distribution line. As such,
they have not eliminated reflections.

Since the customer decides on the load impedance (infinity
when the equipment is disconnected), the power company is
always dealing with mismatched loads. And does not seem
too concerned as long as the load is close to real.

It might be instructive to consider some real transmission
systems. From La Grande-2 (5.6 GW) or Churchill Falls (5.4 GW)
to the first significant load center is about 1/4 wave
at 60 Hertz. Churchill Falls has three 735 kV lines to move
the energy; 1.8 GW per line. At 735 kV, that's about a
300 ohm load impedance. I've seen estimates that put power
line impedance between 100 and 400 ohms. So there might be
a match at full load, but at no load there is serious
mismatch. Of course the generator impedance is close
to zero (feedback achieves this) so there is no attempt
to match at that end. (The above quick analysis ignores
that it is actually a three phase system).

There are apparently serious challenges with keeping
the output voltage down on lightly loaded lines (q.v.
Ferranti effect).

And what happens when the load breakers at the end of
the line trip. 4 milliseconds later the reflected wave
arrives back at the plant. What happens when it hits
the 0 output impedance of the generators?
And how does one stop 11 columns of water 1000 feet
high (500 psi) and 20 feet in diameter before the
generators overspeed?

I am betting there is a story there.

> A standing wave is an amplitude vs position envelope.

Sorry, that is a false statement. Please reference "Fields and Waves in Communication Electronics" by Ramo, Whinnery, and Van Duzer, page 343. The equation for the standing wave voltage is: Ez = Efor*e^j(wt-Bz) + Eref*e^j(wt+Bz)

The equation for a standing wave *envelope* does not contain an (omega*t) term. The equation for the *standing wave* indeed does obviously contain (omega*t) terms since the equation for a standing wave is the sum of the two component traveling waves each containing an (omega*t) term.

If the (omega*t) term is omitted it is an envelope equation, not a wave equation.

We haven't moved forward a bit on that first sentence of the other
post
which is " what created the reflecting voltage" of this resonant
radiator
when it is a fractional wavelength or a electrically full wave length?
Since I am interested in a time varying current for propagation why
should I
worry about anything else ?

This would not be quite correct. The power factor correction
capacitors make the load impedance real, they do not match
the load to the impedance of the distribution line. As such,
they have not eliminated reflections.

Since the customer decides on the load impedance (infinity
when the equipment is disconnected), the power company is
always dealing with mismatched loads. And does not seem
too concerned as long as the load is close to real.

It might be instructive to consider some real transmission
systems. From La Grande-2 (5.6 GW) or Churchill Falls (5.4 GW)
to the first significant load center is about 1/4 wave
at 60 Hertz. Churchill Falls has three 735 kV lines to move
the energy; 1.8 GW per line. At 735 kV, that's about a
300 ohm load impedance. I've seen estimates that put power
line impedance between 100 and 400 ohms. So there might be
a match at full load, but at no load there is serious
mismatch. Of course the generator impedance is close
to zero (feedback achieves this) so there is no attempt
to match at that end. (The above quick analysis ignores
that it is actually a three phase system).

There are apparently serious challenges with keeping
the output voltage down on lightly loaded lines (q.v.
Ferranti effect).

And what happens when the load breakers at the end of
the line trip. 4 milliseconds later the reflected wave
arrives back at the plant. What happens when it hits
the 0 output impedance of the generators?
And how does one stop 11 columns of water 1000 feet
high (500 psi) and 20 feet in diameter before the
generators overspeed?

I am betting there is a story there.

==========

Due to the vast amounts of power generated, we are told it is probably not even possible to solve all of the problems at the utility level. The appliance industries and the utility custromers are held responsible to collectively keep the grid in good order. Governments basically work in behalf of the the utilities by enforcing the design standards via product certification, an interesting cooperative effort by industry and government that works to the extreme benefit of the power companies and the very high cost ultimately paid by appliance customers and ultinately the citizens (consumers). The power company lobbyiosts are very strong: Just look at BPL today (and BPL is just another reason to keep the lines clean).

Over the past 10-15 years, the power industries worldwide have successfully lobbied their governments to clean up the grids by requiring appliances to meet standards like IEC61000-1.-2 etc.. The idea is to get unity power factor in appliances that use significant shares of the grid. Sometimes, capacitors are required on inductive loads (motors etc.) and sometimes inductance is required, for example on products using switching power supplies with capacitive front ends. Almost every PC shipped today that exceeds 75W costs an extra US $0.50 due to a 20mH choke (yes, millihenry) that brings the power factor (cos theta of P-reactive/p-real) to about 0.90. You can notice it when holding the power supply; that choke has a lot of metal mass to it. You can sometimes see this massive thing by peering through the vents of the power supply in your PC. For server products, active power factor correction is more economical and with active circuits, it is very easy to make the cos theta PF is nearly 1 (unity power factor). A number of bad things happen to the grid when the loads become reactive. If you observe the current waveform going into the front end of a typical capacitive front end of a switcher (non-corrected will have a power factor of about 0.60), what you see is a distortion due to the ripple current of the bulk caps in the front end. These distorted currents do 2 very problematic things. First, as discussed earlier, these distorted waves generate large odd current harmomics (square waves are generally summations of the odds), particularly the 3rd, the 5th is usually very high and the 7th. After that, the amplitudes of the harmonics drop quickly and they are not so much a factor (although IEC61000 gives limts to harmonics in the 30th order). These harmonics cause currents to *add* in the neutral conductors of the 3 phase distribution systems. If there were pure sine waves on the system and the loads of the phases were balanced as originally intended, the currents on the neutral would cancel, each 120 degrees out of phase with one another, to zero. I have heard stories of the past years where discussions were made by code writers to leave out the neutral conductors in installations where there were no sever motors loads in the installation (switchers were not invented yet and capacitance was not a problem). The advent of installing hundreds of PC's, servers and other computer equipment in office buildings and elsewhere ended these discusions! Now if you try to eliminate the neutral and just pull phase to phase you will cause the transformers to overheat. For Y systems, the neutral conductors still overheat and cause fires depending on the summation of the power factors of the appliances being used at any given time. For Delta power systems, sometimes the transformers don't even have neutral conductors and the transformers overheat and sometimes even explode. The second problem is that

the distorted current also distorts the voltage sine wave from the power line making it look more like a square wave which is not nice for many applications such as motor loads. So, a lot of this has to do with safety and a lot has to do with good 'stewardship' of the grid in supplying higher quality power. There definitely is an impedance to match to be concerned with; ideal is 50 ohms. Products are universally measured using 'line impedance stabilization networks' (LISN's) of 50 ohms. However, power factor correction does not have to do with matching to the 50 ohm impedance of the LISN; the 50 ohm LISN is only used to provide repeatable measurements.

> think they should be called illusionary waves.
> --
> 73, Cecil, w5dxp.com

I think it is an "important" illusion.

It should be possible to measure, along the distance of the antenna, voltage nodes at maxima and minima distances using instrumentation. A sine wave exists with distance. At the zero points instruments should measure zero voltage. At those nodes, the the current measurements will be out of phase with current over distance. The point is, peak reading meters will measure real values that look like a sine wave dependent on distance, not time. This sine wave is significant.

Pluck a guitar string and you get a standing wave that is an envelope that determines the note. The note depends on the speed of the vibration of the string which is determined by its wavelength (like a VSW, it is also a distance wave). The wavelength multiplied by the speed of the vibration becomes the frequency of the note. The note becomes sound which moves at a different speed, i.e.a traveling wave at the speed of sound, not the speed of the vibration. Kinetic energy converts to acoustic energy. The vibration is not an illusion, it really exists. It determines the frequency of the sound energy that its kinetic energy is converted to, and, it can be physically observed. So it is a bit more than an illusion. In RF, the standing wave merely determines the frequency of the effeiciently transmitted EM wave, it is not the EM wave itself.

The RF standing wave is important in that it it's WAVELENGTH (distance), like the guitar string, also determines the frequency at which the EM radiated frequency (like the musical note) is most efficiently transmitted in a resonant antenna (like the guitar string), where f = c/wavelength (just like the guitar string but substituting c for the speed of the string vibration (not speed of sound))). Does this make sense?

The wavelength of the RF standing wave (a distance measurement) determines the frequency of the RF "note" that ends up being radiated.

And remember that time t is just another dimesion just like distance x,y,z
in a space-time continuum, so what is wrong with the concept of a "distance
wave"
;-)

Art wrote:
"So I added a time varient to a static field which provided a direct connection to Maxwell`s laws."

It is said that Maxwell began with Faraday`s law of electromagnetic induction, which seems reasonable, as the voltage in one loop of wire inductively coupled to another is proportional to the derivative dphi/dt of current produced magnetic flux from the primary loop.

Induced voltage does not arise at a single point on the loop but is the sum of all the infinitesimal bits of voltage distributed around the loop. Maxwell developed his first field equation from this start.

Faraday`s law already deals with a time varying current to obtain induction.

Different derivations are possible but Maxwell`s equations can express all known electromagnetic conditions at once.

Oliver Heaviside made it his job to study Maxwell`s "Electromagnetic Theory", learn its mathematics, and reduce it to vector analysis. Heaviside published his results beginning a series of papers in 1887 in a British publication, "The Electrician", in a very understandable way. This has been called the start of modern communication engineering.

Art also wrote:
"The result for equilibrium must be a tank circuit where all energy is interchanged between the energy storage tanks (inductance and capacitance)"

True that an EM wave exchanges its energy between an electric field and a magnetic field. Not true that a tank circuit type antenna is needed to launch or capture EM waves. An isolated wire, resonant or non-resonant is all that`s needed if it carries alternating current.

Nor are explosives needed to generate radio waves. Less disruptive methods are quite acceptable.

Art also wrote:
"The bottom line is that for best efficiency for the unit volune supplied to an array must be in equilibrium."

The above doesn`t square with what I`ve seen.
Efficiency is output over input. Antenna efficiency is usually Radiation Resistance / Radiation Resistance + Loss Resistance. For the most antenna for the money, Terman suggests the Yagi or the Corner Reflector.

Enough debunking for tonight.

Best regards, Richard Harrison, KB5WZI

can we do this... Maxwell did not write 'laws'. all of my references refer to "Maxwell's equations". Maxwell collected laws from Faraday, Gauss, Ohm, Ampere, and probably a few others and as far as I know added just the displacement current concept to turn them into a concise description of time varying electromagnetic phenomenon that has never been disproved. This set of equations is indeed what all antenna, feedline, waveguide, motors, power transmission, and related electromagnetic phenomenon are modeled with successfully in all environments that we have experienced. (neglecting things like black holes anyway) This includes diamagnetic, paramagnetic, ferromagnetic, insulators, conductors, dielectrics, and even the new man made negative refractive index materials. it is not necessary to add a new 'time varient' part to any of Maxwell's equations, they already contain all the time variant parts that are needed to explain any electromagnetic fields you can come up with.

> charge, and hence no energy, flows.

absolutely correct. no charge flows through the insulator of a capacitor.
you don't have to try hard to set up this condition, it is true of any
capacitor that has no resistive losses. the concept you are struggling with
is called the 'displacement current'. This is the unique concept that
Maxwell added to the laws of Gauss, Faraday, et al when he compiled his set
of electromagnetic equations. once you understand that then all will become
clear.

>> 2. I don't understand the mechanism which causes waves to bounce.
>
> I take this to imply that you are not happy with the simple "like
> charge
> repels"?
>

waves do not bounce. waves superimpose on each other, but the original
waves that meet in a homogenious, linear medium DO NOT INTERACT in any way.
they each proceed happily on their way without any change. it is only due
to the limited capability of your measurement instruments to measure the
superimposed field that results that causes the confusion. if you could
easily separate out the forward and reflected waves it would become
intuitively obvious... however the poor instruments (swr meters and other
'power' meters) that have caused the confusion and resulted in the misnomer
'standing wave'. It is of course not a 'wave', nor does it 'stand'... it is
just the result of superposition of 2 waves traveling in opposite

directions.

> So the (poorly developped) "charge bouncing" explanation
> seems like a way out, but I certainly would appreciate
> other explanations for consideration.

you don't need a 'way out' you need to go back to basics and learn the proper explanation.

>> A large part of the argument seems to revolve around a single point in a
>> perfect transmission line, where the current is exactly zero. This is an
>> infinitesimal point on a perfect line, so some anomalous things might be
>> expected to happen there.

but the current, or voltage, is only zero because of the superimposed oppositely traveling waves. it is only your poor measurement instrument that only responds to the superimposed waves that causes the confusion.

there. that ought to cause enough controversy to push this thread over the 1000 mark pretty quick! the wx is bad and i needed something to do today anyway since i can't go out and work on my maxwell compliant antennas.

It's a little more complicated than that. If the voltage and current are actually brought into phase all along the transmission line, the system is indeed a traveling wave system free of reflections. If the power factor is exactly 1.0 at all points up and down the line, the line is flat, i.e. matched by definition. Of course, it's not a perfect system and the power factor is rarely exactly 1.0 so the system usually exhibits signs of a mismatch, an overhead expense for the power company.

The characteristic impedance of the horizontal wire above ground is in
the neighborhood of 600 ohms. The "load" impedance at the end of the
wire can be considered to be infinite. The reflection coefficient at
the tip of a dipole is 1.0, i.e. all the forward voltage is reflected
in phase. This is true no matter what the length of the dipole. The
round trip delay that the forward wave makes can be used to get a fair
approximation of the feedpoint impedance using transmission line
equations and assigning an appropriate value to the alpha loss factor
which not only includes real losses but also "losses" due to
radiation.

By "illusionary", I certainly didn't mean "imaginary". A magician's
act contains illusions based on real events. It's just that the
audience doesn't comprehend what is really happening. That's exactly
what is occurring here with standing waves. The standing waves, like
the magician's illusions, certainly have a real existence but many of
the conclusions about standing waves that are presented here are based
on the illusions created by those real standing waves (which do not
meet the definition for EM, i.e. photonic waves).

Thanks for the reply Cecil which has opened my eyes regarding the
trend of your thoughts.
Try to change your thinking to the following. An alternating current
is created by a generator
that moves in a circular fashion. The + and _ functions are a
mathematical tool obtained by the sine .cosine etc. This is a measure
ONLY of the amplitide only at a particular point in time. If you put a
scope on it you will see a wave like function only because your eyes
e.t.c.
is not fast enough to take more samples at the point in question. Thus
it is an illusion to think of forward travel. Another way of looking
at it is to stand in the center of a football field and watch the
spectators stand up in sequence. At any point of what you are viewing
you /
your eye mechanism,are seing a movement upwards at a single position
at a single point in time.
At no time is there anything moving forward thus this reflection of
yours cannot occur.
I think we can end out interchange at this point
Very best regards
Art Unwin KB9MZ....xg(uk)

Hi Stewart

I was aware that my "stub' comment was brief. Whenever I am unsure of
the knowledge level of a reader, I assume they know at least as much as Ii
do.

My suggestion for eliminating the DC path thru the antenna coax is to cut the coax *outer conductor* to make a small gap. Perhaps a 5 mm gap is reasonable. It could be a 10 mm gap. Just dont make the length of the gap in the outer conductor excessively wide.

Make a length of coax that is slightly over 1/4 wave long. Lets assume you use RG 58 and it has a velocity factor of 0.66 and the operating frequency is 850 MHz. A 6 centimeter length of RG 58 with one open and the other end trimmed to allow it to be connected across the gap.
The outer conductor of the stub is connected to the outer conductor of the "phone coax". The inner conductor of the stub is connected to the other side of the gap in the "phone coax".

The thought beneith this plan is -- A quarterwave open circuit length of transmission line looks like a Short Circuit at the other end.

It might be interesting to even make something more elaborate to DC isolate the coax line. A pair of discs with a quarterwave radius would be very interesting. A set of concentric tubes into which the coax could fit, could be a more attractive way to get DC isolation while the RF path is retained. But, first,I'd try the system when only a short length of open circuit coax bridges the gap.

I added a time varient to GAUSSIAN law to make it the same as
Maxwellian laws, not the other way around as you are inferring.
Before Maxwell came a long there were multiple laws stated many
different ways.
Maxwell saw that many of these laws tho written differently condensed
to the same thing.
So he condensed these multiple laws to a few but an no time did debunk
the laws that already were in situ. All of these multiple laws as with
Maxwell were built on the shoulders of Newton
and those that contributed before him, all of which are derived around
the pivot of gravity
and equilibrium

Hi Keith,

I think you are putting too much emphasis on the measurement of energy in the pulse, or maybe not enought, depending upon how you are making and using the measurements.

I hope you agree that the transmission line you are pulsing has no standing waves. If not, then the pulse must be a treveling wave. If it is a traveling wave, the impedance of the wave will be the impedance of the transmission line, except where the two pulses cross paths. At the crossing point, the impedance will jump to infinity, Z = v/i = v/zero = infinity.

How about the energy/power levels? Except at the center, as the pulse passes, current and voltage can be measured, so power is being delivered from one section of the line to a second section more distant from the source. The energy delivered by the power equation can be measured by U = (v^2)/r = (i^2)*r where r is the Zo if the transmission line.

Where the two pulses cross, the energy level must be the sum of the two energy levels, which would be 2U = 2*(v^2)/r (assuming two pulses of equal voltage). As you have pointed out, power would not flow at the point of wave first meeting, spreading from the meeting point back towards the two sources a distance equal to the square pulse width. Energy is present however, measured as U = (v^2)/r.

The transmission line can be considered as a lineal capacitor, so U = (CV^2)/2, where C is the capacitance per unit length. If the waves "bounce", and occupy physical space for a period of time, they should comingle, stop, and fill the capacitor during that time. If so,

2U = C*V'^2
= 2*(V^2)/r where v is the voltage of a single pulse and V' = 1,414*v = voltage observed at point of crossing.

At a disconinuity, we find a doubling of the voltages, not an increase of 1.414. This leads me to believe that the crossing pulses never stop in a physical sense. They do stop in the sense that power is not delived through the center point.

Roger you are conversing with old men most of which oppose change.
Having been taught some fifty years ago they want to protect those
teachings the originators of which are all dead.
Thus regardless of what has happened and discovered or intruded upon
by inquiring minds they wish to stay in the past.In the past, statics
was viewed as a subset of electro-dynamics and the old timers want it
to stay that way. By starting with Gauss and adding a time varient I
added a visual to Maxwell that was missing from his equations because
Gauss was not the leading
contributor to the time varient theme. It is this that the old timers

are resisting because it brings away the thought that statics is just a subset. Thus you see that there is inherrent resistance to the mathematics that supplies a visual to Mawellian equations. It took Richard several months to accept the legitimacy of the mathematics involved in the steps I took. As yet nobody else has admitted to the legitamacy of the mathematics. Thus protecting the notion of static being just a subset. This manoever has placed ham radio into a quagmire from which they cannot extricate themselves and thus advance to analyse the intricacies of propagation.
Who would have believed that ham radio would take to task of a Doctor working at MIT on space reseach for NASA for faulty use of mathematics to prove the relavence of statics?
Can science really be held up while old men are still living?

Cecil,

That is flat out wrong. For a plane wave the E and H fields are perpendicular for either traveling waves or standing waves. For a coaxial cable operating in the normal TEM mode, the E field is radial and the H field is circular around the center conductor. Again, the E field and H field are always perpendicular. Unless one or both of the fields are exactly zero, the Poynting vector will be nonzero. It will have a magnitude and direction.

I suppose what you are looking at is some sort of time average. In that case the average of the Poynting vector at a single point in space may be different for standing waves and traveling waves. However, that information is essentially useless. The only thing with physical reality, related to Poynting vectors, is the integral of the Poynting vector over a closed surface. Equivalently, the only thing with physical reality is the divergence of the Poynting vector.

In the lossless cases we are typically discussing, the time-averaged integral or the divergence is exactly zero for either the traveling wave case or the standing wave case. The Poynting vector is no help in making any sort of distinction at all.

Cecil,

I have been doing that for decades. Is there some tutorial material I seemed to have overlooked? (other than RRAA, of course) I already have tons of books on physics, engineering, and optics.

What do you recommend as the definitive reference on "the nature of photons and photonic waves"?

argh, another misconception!.. the impedance of a transmission line doesn't change! and the impedance seen by a single traveling wave never changes either. the measured ratio of voltage to current at a point on the line can change as a result of the superposition of traveling waves. but again, that is just a result of cheap instrumentation that can't resolve the component waves.

Roy, W7EL wrote:
"A Bruene wattmeter circuit measures "forward power" and "reverse power" just fine simply by measuring the voltage at a single point on the line."

So does the Bird Thruline Wattmeter., and it has been doing so for about half a century.

It uses the fact that reflection reverses the phase between voltage and current on a 50-ohm coaxial line. That means forward waves can be separated from reflected (reverse) waves. Bird designs its measuring elements to extract a line voltage sample that causes the exact same meter deflection as does a line current sample.

From a wave traveling in one direction the samples add. From the wave traveling in the opposite direction, the samples exactly cancel in the meter. Voila! a directional coupler.

It was A14QJ who wrote:
"The components of the superposition wave no longer exist by themselves;----".

My reply was:
"The components are not cancelled. Were that so, the Bird Thruline Wattmeter could not function and the standing wave would be independent of the forward and reflected waves. Instead it is only a manifestation of interference."

I don`t have a Bruene wattmeter, but I believe it functions like a Bird but uses transformers to couple to the transmission line.

Hi Roger,

I'm not sure if this is original to you, or one of those conceits that
is being passed around; but how, short of tagging energy (power?), can
you tell its origin? In other words, delivery by return, or
completion of the path needs to be separable by some information about
the origin that to this point has been missing from the discussion.

If energy can be tagged with a return address, what is that tag?

Gene Fuller wrote:
"You know exactly what capacitors are for, and it isn`t to control transmission line reflections from open ends of the line."

When you open a circuit at an instant when current is flowing, the transient created can be large. Natural phenomena also create injurious spikes on a power line. Capacitors absorb transient current reducing and delaying a voltage rise which gives overvoltage protection a chance to operate.

Lightly loaded induction motors cause power factor to lag, demanding additional current. Capacitors to correct large amounts of lagging current often take the form of over-excited unloaded induction machines (rotory capacitors) which produce an offsetting leading power factor.

Power loss in power lines is proportional to the square of the current, whatever the cause, so power factor correction aims at to reduce current in the line.

Best regards, Richard Harrison, Kb5WZI

Ah. Apparently the only book you know of that contains the
description of a standing wave.

> The equation for the standing wave voltage is: Ez = Efor*e^j(wt-

And when Ramo and Whinnery, for example, plots standing wave current
on a vertical radiator, for example, why do you suppose it looks like
an amplitude vs. position curve?

> If the (omega*t) term is omitted it is an envelope equation, not a
> wave equation.

Ah. So according to Cecil, we have a new definition for a wave which
now stipulates that it must only be expressed as a function of time.

If you only knew how ridiculous you sound.

Good point. It would have been much better to say something like :"At the
crossing point, the MEASURED impedance will jump to infinity (Z = v/i = v/zero =
infinity) but we have no indication that the impedance of either the wire or the individual
pulse changes in any way.".

Current is the tag, and the address is "past" and "future". Measurement is always "present", but we like to make predictions about what will happen in the future, and trace what has happened in the past. With the electromagnetic equations, we are quite good at making those extrapolations from present measurements.

At the crossing point, we can not measure current, so the power equation of P = V * I fails. There is no power at this point that we can measure. We can measure instantaneous voltage but don't know which equation to use to determine energy, U = (CV^2)/2 or SumU = Sum((V^2)/r). Only if we make many measurements over time can we learn the shape of the voltage over time, and thereby deduce which equation to use.

Hi Roger,

Hence the information as to the source of energy that arrives at its
final destination is completely lost.

Barring this tracking, then, there is no way to prove effects due to
the "crossing point."

So, why does this discussion proceed without hope of any meaningful
proof? Certainly, given more than 400, 500, 1000 postings there must
be some other tagging mechanism that you are unaware of, or has been
withheld from comment. Did we miss that announcement?

Hi Art,

Like you, I would like to find a better way of doing things, especially some easier math for the electromagnetic equations. Until we find that better way, we must use what we have.

What we have is very, very good, because it has brought us TV, computers, the Internet, space travel, and much more. What ever we find that could be "better", must also contain the knowledge we have today, but perhaps can explain todays knowledge easier or more completely.

I try to learn from the old men because the sum of their knowledge is far greater than my own can ever be. Having said that, I also recognize that the knowledge of each man is limited by his own talent, experience, and human frailty, so a judgement must be made as to wisdom and accuracy.

I really admire the willingness of all participants to contribute to discussions. The hard part is knowing how to fit each new tibit of knowledge into my own personal knowledge base.

I personally like "Optics" by Hecht and his idea that standing waves
maybe shouldn't be called waves at all. EM waves move energy and
conserve momentum. Standing waves don't.

The absolute confusion eminated by Americans regarding 'Standing" and "travelling" cannot be used as a absolute condemnation of American education.Freedom of speech is a basic right, the downside of which it is that it reveals the speakers level of education.However, the confusion alluded to is primarily that of old ,unemployed or retired people. In all of these cases a resume can be expanded way beyond that knoweledge level when the resume is overseen by an employer but with the excuse of advancing age and poor recall of memory the resume can be expanded to reflect the perceived expertise that the owner feels that he has attained by using a transmitter. If a employer were to review the resumes of these self esteamed applicants they can be excused in their efforts to find suitable applicants overseas. But this newsgroup is the world of old people, so one must constantly remind themseves that this world is not representitive of the new generation who may well be able to accept change but also posses a level of inquisitivenes.
True, the quest for offshore employees by the present day employer may well reflect that the old also represent the young which if accepted, point to a nation in decline where advances in science can be purchased and its inhabitants can be ignored. Brings back memories of Japan and the Yagi antenna. Only after the war did it recognise the value of home built advances ala the antenna invention,while other nations pounced on science as a mechanism to achieve a better life for their own natives. It is noble to supply education to all that pursue such, but when educators dumb down the education for personal monetory reasons they trade a country for momentary rewards.
What goes around comes around the same way as did perceived empires of old.
Best regards
Art Unwin KB9MZ

A standing wave has an associated envelope but the envelope is *NOT*
the wave itself.
It's like saying the body of a car is the car itself but you have
forgotten the thing that makes the car move - the motor.

> > Sorry, that is a false statement.
>
> No, in the most general sense, it is a precisely accurate statement.

The equation for a standing wave contains an omega*t term. The
equation for standing waves that does not contain an omega*t term is
the equation for the envelope. Quoting the following reference, page
32: "For problems in which we shall be concerned throughout with
sinusoidal quantities, it is not necessary to write the factor e^jwt
explicitly each time, since it will always be understood that all
terms are multiplied by this factor;"

Ramo and Whinnery use E+ and E- but that looks too much like addition
and subtraction when using ASCII characters.

> Ah. So according to Cecil, we have a new definition for a wave which
> now stipulates that it must only be expressed as a function of time.

Nothing new. The actual standing wave equation is a function of time.
Dropping the time term turns it into an envelope equation. An envelope
is a wave envelope, not a wave. You need to learn to be a little more
precise with the language you choose to use. Looks like you have

forgotten that e^jwt is implied. You need to be a little more precise
with your wording.

wrote:

>The writtings of many of us still have "hope".

Hi Roger,

Ah, yes. Hope without proof is called faith. There are testimonials,
and there are witnesses to miracles - however, those, too, seem to be
far and few between.

Faith in "what" seems to be an even greater mystery, and a strange
basis for belief.

Another conceit I've seen ripple through the threads - I don't think
you offered it either, but authorship is vague - is that this "what"
may be waves bouncing.

Hope in waves bouncing (for which only faith supports this where proof
is absent) may solve the mystery of "what," but like Russian Dolls
nested one inside another, certainly this faith is ever spiraling out
toward some even greater mystery in beliefs.

To put it in religious terms: "So What?"

Is this the road to redemption?

Is it like the discovery of the mirror? Did the discoverer (inventor
if you will seeing as the mirror might be currently in the process of
patenting) attain a new insight? a new perspective?

Even there, our using (measuring with) a mirror gives us a means to
tag information through parallax. Is this thread missing something as
simple as parallax to tag currents as to their origin? It would seem
after 800 contributions that this contribution (parallax) would have
resolved the thread and brought closure to allow everyone to transcend
obstacles on that road to redemption.

Is anyone actually pursuing the goal of finding and expressing the
parallax problem (or revealing any tagging); or are they simply
content to have hope and wait for the end of days milling about the
edges of the purgatory of Babel?

This was not the line I meant. My line was perpendicular to the
plates.
Current does not cross this line because it arrives equally from both
sides.

Or is it the "standing wave" which is real and it just happens that
it can also be described as the sum of two waves going in opposite
directions? But the wave going in one direction can be described
as the sum of a number of waves going in that direction? (Especially\
when there are multiple reflections!) How many waves in each
direction?
When do we stop?

I respectfully submit that it is only the resultant that is real.
The rest are merely alternate descriptions (though often useful).

> I think you are putting too much emphasis on the measurement of energy in the pulse, or maybe not enought, depending upon how you are making and using the measurements.
>
> I hope you agree that the transmission line you are pulsing has no standing waves.

"Standing waves" seem to more be a consequence of sinusoidal
excitation than pulse.
So I expect no "standing waves".

I don't even like using the words "traveling wave" to describe the
pulse situation
since "traveling wave" also seems to bring a lot of baggage.

> If not, then the pulse must be a treveling wave. If it is a traveling wave, the impedance of the wave will be the impedance of the transmission line, except where the two pulses cross paths. At the crossing point, the impedance will jump to infinity, Z = v/i = v/zero = infinity.

I do not recommend computing this ratio and calling it impedance. I
find it leads
to difficulties. Better just to think of the V and I independantly.

> How about the energy/power levels? Except at the center, as the pulse passes, current and voltage can be measured, so power is being delivered from one section of the line to a second section more distant from the source. The energy delivered by the power equation can be measured by U = (v^2)/r = (i^2)*r where r is the Zo if the transmission line.

More accurately P(t) = V(t) * I(t). it happens that for the pulses in
question,
except when colliding, that V and I of the pulses observed on the line
are related
by Z0 so by substitution, the expressions above can be derived. But
sometimes it is
better to stick with the more basic expression P=VI.

> Where the two pulses cross, the energy level must be the sum of the two energy levels, which would be 2U = 2*(v^2)/r (assuming two pulses of equal voltage). As you have pointed out, power would not flow at the point of wave first meeting, spreading from the meeting point back towards the two sources a distance equal to the square pulse width. Energy is present however, measured as U = (v^2)/r.
>
> The transmission line can be considered as a lineal capacitor, so U = (CV^2)/2, where C is the capacitance per unit length. If the waves "bounce", and occupy physical space for a period of time, they should comingle, stop, and fill the capacitor during that time. If so,
>
> 2U = C*V'^2
>   = 2*(V^2)/r where v is the voltage of a single pulse and V' = 1,414*v = voltage observed at point of crossing.

But the voltage at the crossing is 2V. A puzzle? When the pulse is
"travelling",
there is energy in the capacitance and in the inductance of the line.
When the

current stops, the energy in the inductance is added to the energy in
the
capacitance, thus the voltage reaches 2V.

> At a disconinuity, we find a doubling of the voltages, not an increase of 1.414. This leads me to believe that the crossing pulses never stop in a physical sense. They do stop in the sense that power is not delived through the center point.

I suggest that since the current at the middle of the line
is always 0, the power is always 0 and therefore no energy
crosses the middle. While tracking mixed energy is difficult,
when no energy crosses a boundary it seems easy to keep the
energy on each side of the boundary separate.

huh?? no charge passes from one plate of a capacitor to the other. but current does in the form of displacement current. if you are trying to look at the microscopic field and charge distributions during a transient in a capacitor you are way beyond anything i ever studied, or would want to study.

>> waves do not bounce.
>
>What about charge?

charge is being moved by the fields of the wave, and it moves very little in the wire as has been shown in the past. when equal and opposite waves arrived at a point where the current cancels the charges superimpose to result in a zero field so there is no motion, hence no current at that point. as the waves pass each other the fields no longer cancel so the electrons on the other side of the cancelation point start to move again in the opposite directions. if you want to call that a bounce knock yourself out, but it will lead to a rather limited view that is only helpful in certain circumstances where exact cancelation occurs.

then enjoy your fantasy. the forward and reverse wave components are easily separated and observed anywhere on the line. its just that most amateur grade equipment doesn't bother because it is sufficient for 99.44% of us to only measure your 'real' standing wave to properly adjust our antennas and radios.

Hi Keith,

If you cannot identify the source, then you cannot proclaim a
separation.

The best term for this is "the enigma effect." I hate to turn this
loose on the world because I know many here will pick it up and run to
their perceived goal for a touch-down.

Before anyone tackles me for a touchback, I'm going to pass this off
and watch the quarterbacks wrestle with religion in the huddle.

Keith,
Richard has not entered the actual discussion nor has he shown any
indication
he understands what is going on. All he is doing is intimating he
knows all the answers but he is not going to reveal them. Why? He has
no choice if later he wants to state "I knew that all the time". In
the mean time he is taunting people with off subject topics and then
deigns not to provide technical content. He is very good at arousing
people to respond to him in a defensive manner as you can now
personally point out, usually by asking questions without any effort
to support the discussion.His degree is in english which is why he is
practicing on this newsgroup
Have a great week end

True for traveling waves. ABSOLUTELY *FALSE* FOR STANDING WAVES. Those false concepts are the source of your (and others) confusion.You should have paid attention to my postings of those two very different equations.

The E and H fields are 90 degrees apart for traveling waves. The cross product of ExH is the power density in watts/unit-area, i.e. the Poynting vector. For standing waves, the E and H fields are either in phase or 180 degrees out of phase. The cross product of ExH for standing waves is *ALWAYS* equal to zero, i.e. the Poynting vector for pure standing waves is always equal to zero. Please alleviate your ignorance on this subject and get back to us. There is ZERO real power in a pure standing wave. The Poynting vector for a standing wave is *ALWAYS* zero contrary to what you falsely assert above.

Stating the same thing in voltage and current terms, for a traveling wave, the voltage and current are either in phase for forward waves or 180 degrees out of phase for reflected waves. Either way, the real power in the traveling wave is V*I watts.

For a standing wave, the voltage and current are 90 degrees out of phase. The real power in the standing wave is ZERO! P = V*I*cos(90) = 0

Of course, what you say is only true for net energy. If we have a
forward Poynting vector of 100 watts and a reflected Poynting vector
of 100 watts, no net energy is flowing at any point.

To single out a particular spot as the site of a lack of energy movement along an equipotential system in which there is no tranfer of energy anyway seems to me to be an arbitrary convenience.

Maxwell explained how electromagentic waves 'bounce' if they encounter matter, and I haven't seen any evidence that it was an incomplete description.

Which is correct? P = (v^2)/r = (i^2)r or P = (v^2)/r + (i^2)r

If P = (v^2)/r = (i^2)r is correct, what is the precondition that MUST be true?
Answer: The i and v measurements must be across a pure resistance, without reactance.

The traveling wave is considered to have a pure resistive impedance.

This going by measurements makes things hard! Too bad we can't see and feel the wave with our own eyes and hands!

>

Cecil,

That is utter nonsense. Back to school for you. You are confusing phase, vector direction, phasors, and most everything else. What a mess!

Everything I said above is exactly correct.

73,
Gene

That was a joke. I doubt that Hecht even uses the exact term "photonic wave". For fun, try a Google on "photonic wave". Most of the entries are really weird stuff.

Wave-particle duality means that light and other electromagnetic phenomena can be described in terms of waves or in terms of photons. There is no need to use both descriptions at the same time. The laws of physics are complete for either.

>
> Which is correct? P = (v^2)/r = (i^2)r   or   P = (v^2)/r + (i^2)r

P(t) = V(t) * I(t)
by substitution from V = I * R
P(t) = V(t) * V(t) / R
and
P(t) = I(t) * I(t) * R

But recall that power is the flow of energy per unit time.

The energy present in any section of line is the energy
present in the electric field of the capacitance plus
the energy present in the magnetic field of the inductance.

So from your expressions above
U = (CV^2)/2 + (LI^2)/2

> If P = (v^2)/r = (i^2)r is correct, what is the precondition that MUST be true?
> Answer: The i and v measurements must be across a pure resistance, without reactance.

This is why it is often better just to use the original
equation:
P(t) = V(t) * I(t)
for it is always true and requires no preconditions.

 This leads me to believe that the crossing pulses never stop in a physical sense. They do stop in the sense that power is not delived through the center point.

That is hardly difficult. If no energy every crosses
the middle of the line, then the energy on the left half
of the line originated with the source on the left side
and ditto for the right.

Actually, what you don't seem to realize is that exactly the same laws
apply to both at the same time and all those laws are perfectly
consistent. Photons cannot stand still. Therefore, standing waves are
not photonic, i.e. they are not EM waves. That you assert the standing
wave E-field and H-field are 90 degrees apart is insanity (in addition
to being completely false).

Hi Keith,

If indeed.

The difficulty is you've already allowed that the energy is not
tagged, so its source is unknown at the load. So "if" fails through
this immutable correlation. The separation is not demonstrated.

> of 100 watts, no net energy is flowing at any point.

You don't need Poynting vectors to realize that when
the instantaneous power is always 0, no energy is flowing.
And when the instantaneous power is always 0, it is
unnecessary to integrate and average to compute the
net energy flow, because no energy is flowing at all.

And if by your response you really do mean that energy
can be flowing when the instantaneous power is always 0,
please be direct and say so.

But then you will have to come up with a new definition
of instantaneous power for it can not be that it is
the rate of energy transfer if energy is flowing when
the instantaneous power is zero.

I got a Shakespeare Loran C antenna for pennies, but don't know if I can use it for another application. I'd like to use it for CB, VHF (marine), or 2 meter. Any thoughts?

Thanks,
Bill L.

That antenna was designed to operate at about 100 khz. I doubt that you would find it useful for about anything as it is. If you could get it apart with wrecking it. You might put in a vertical dipole to use it for 2 meters or marine vhf.

Hi Bill,

The last antenna that I had used for that purpose was 30+ years ago,
and it could suitably be used for CB/10M perhaps lower, and perhaps
higher to 6M. It was nothing more complex than what it appears to be:
a 3 to 4 meter tall whip worked against a metal superstructure. You
will, of course, need to match to it.

Correct.
>
> But recall that power is the flow of energy per unit time.
>
> The energy present in any section of line is the energy

When the capacitance is in phase with the magnetic field, both are measured to peak at the same time. This "resistive" condition is found in a transmission line when there are no standing waves. Under resistive conditions, the electric field and inductive field merge into one electromagnetic field that carries only one energy. The identical charges carry both electric and magnetic fields, with the fields in a ratio defined as impedance. Each field is a separate way of looking at the same energy.

> So from your expressions above
> U = (CV^2)/2 + (LI^2)/2

You may have been reading about traveling waves. They offer an explaination for how magnetic and electric fields may get out of phase. When the two fields are out of phase, the U = (CV^2)/2 + (LI^2)/2 calculation will ALWAYS sum to more energy than can be found in the resistive wave. This occurs because more energy actually is resident on the line with reflections, due to waves traveling in two directions. The reflection effectively doubles

the length of the transmission line available for energy storage.

>

I learned long ago that it DOES have a precondition. The power measured will only be resistive if measured across a pure resistance. If the measurement is across resistance plus reactance, then reactive power is also measured so P(t) = V(t) * I(t) becomes the sum of an unknown mix of two or more waves.

Take two flashlights.
I claim that the energy for the light produced by each
originates in the battery in each flashlight.
Is your claim otherwise?

Connect the negative terminals of the batteries together.
I claim that the energy for the light produced by each
still originates in the battery in each flashlight.
Is your claim otherwise?

Connect the positive terminals of the batteries together
through an ammeter. For the purposes of this experiment,
the batteries have exactly the same voltage so the ammeter
indicates that no current ever flows between the batteries.
I claim that the energy for the light produced by each
still originates in the battery in each flashlight.
Is your claim otherwise?

I am not quite sure what you are attempting to say here and
whether you are disagreeing with my assertion that the total
energy in a section of line is equal to the sum of the energy
present in the capacitance and the energy present in the
inductance.

> > So from your expressions above

This seems like a complicated way to think about things. So
complicated that I will
not comment on correctness.

This too seems like a complicated way to think about things.

P(t) = V(t) * I(t) is simple, and always holds. One does not need to
consider
the wave content in any way. Or impedances. Measure the instaneous
voltage and
the instanteous current; multiplying will always yield the
instantaneous power.
Integrating instantaneous power will always yield the net energy
transfer over
the interval of integration.

Art,
Face it, you are getting old too. I only know of one way of not
getting any older, not presenting the normal characteristics of
getting old(er). Dress it up anyway you want, that fact still holds
true, I don't care if you wear "baggies" or not. If you're gonna wear
them baggies just remember that them boxers are required too. Only
alternative is an 8" piece of duck-tape applied vertically and
centrally, posteriorly. Otherwise, you just show your ass like in
that last post. Unless you present the 'other side' of the
conversation you seem to be having, it just ain't gonna make much
sense.

It must upset you something fierce then to know that the founders of the major Ivy league schools and some of the most wealthy and influential people today all have a common trait, they do not hold a collage diploma.

In answer to your condescending posts that I have ignored to this point I reply "do something". This is not meant to be combative, but an observation of fact. Some people lose sight of what a education is, a tool. They simply marvel at the tool without putting it to good use.

If your ideas are superior to the current art, why not put them to good use to the betterment of mankind? This will make you much more sought after than a bitter old man taking jabs at passers by.

I look forward to a useful application of your ideas.

Regards,

Chris

In power engineering, the power can consist of two components, active
power, V*I*cos(A) = watts, and reactive power, V*I*sin(A) = VARS.
These terms are defined in The IEEE Dictionary. P=V*I results in
Volt*Amperes, part active and part reactive if the voltage and current
are not in phase.

> Everything I said above is exactly correct.

Sorry Gene, almost everything you said about standing waves is false and some simple math will prove it. Please stop acting like a spoiled brat long enough to understand the following facts of physics.

Assume the forward wave and reflected wave have the same magnitude. At one point on the line:

The forward voltage is 100v at 0 deg and the forward current is 1 amp at 0 degrees.

The reflected voltage is 100v at 90 degrees and the reflected current is 1 amp at 270 degrees. Perform the simple phasor addition to find the magnitude and phase of the standing wave at that point.

The standing wave voltage is 141v at 45 deg and the standing wave current is 1.414 amps at -45 deg. The standing wave voltage and current are *always* 90 degrees apart which means the standing wave E-field and H-field are necessarily either zero or 180 degrees apart.

141*1.414*cos(90) = zero watts = ExH = E*H*sin(A) = standing-wave Poynting vector

Therefore, the angle A between the standing wave E-field and H-field is either zero or 180 degrees. That doesn't meet the definition of a TEM wave. Therefore, standing waves are *NOT* TEM waves and Hecht was right about that notion.

Until you (and others) hit the books and correct your false concepts, you are going to continue to exhibit your considerable ignorance of this subject, your alleged education notwithstanding.

I believe that, in the long run, the technical truth will will out over all the ignorance, obfuscation, and ad hominem attacks.

Hi Keith,

You have admitted that energy dissipated in the loads cannot be
identified to its source and you have used the above devices previous
to that statement. Your admission dismisses their applicability.
Separability is not demonstrated.

> But one must remember the units of that result is Volt*Amps, not
> watts.

You really should put a bit of effort into understanding
the different expressions for power.

P(t) = V(t) * I(t)

is saying that the function which describes power with
respect to time, P(t), is the product of the function
describing voltage with respect to time, V(t), and the
function describing current with respect to time, I(t).

As corollary, the power at an instant of time is equal
to the voltage at that instant times the current at
that instant.

And, of course the unit watts is the same as the units
volts times amperes. Just do the substitution.

V = J/C
A = C/s

V A = (J/C) x (C/s)
= J/s
= W

You are confused with the common use in power
engineering where VA is used to mean Vrms*Irms.
Whether VA is equal to watts depends on the
phase relationship of the voltage and current.

When the voltage and current are not in phase, then
the expression
Pavg = Vrms * Irms * cos(A)
can be used to derive the average power.

This is a special case of P(t) = V(t) * I(t).
It is applicable when V(t) is a sinusoid of
a single frequency, and I(t) is related to V(t)
using the expression V(t) = Z * I(t).

Pavg = Vrms * Irms * cos(A)
is completely derived from P(t) = V(t) * I(t)
by appropriately substituting for V(t) and I(t)
and then averaging P(t) over an appropriate
interval (typically one cycle).

Bottom line:
P(t) = V(t) * I(t)
is always correct.

The other variations only work when
applied under the appropriate conditions.

IF the Loran Antenna has a Screw-in Whip that mounts to an Antenna
Coupler/Amp, and the whip is about 108" long, THEN the whip is a standard
CB Style 108" whip, commonly used for Loran reception, and is generic,
like ALL other 108" whip antennas. The thing that makes a 100 Khz
antenna for Loran-C is the Antenna Coupler, that the whip Screws into,
which has a 100 Khz Preamp, and filter built in.

You obviously mean the *real* instantaneous voltage times the *real*
instantaneous current. You should say that to avoid confusion.

Seems you need to add 'Re' to that equation to remove the obvious
ambiguity. P(t) = Re[V(t)]*Re[I(t)]

From "Fields and Waves", by Ramo & Whinnery:

W(t) = {Re[Vm*e^j(wt+A1)]}{Re[Im*e^j(wt+A2)]}

This is very well-stated. There is no real power dissipated by the "standing
wave" envelope.

Gentlemen and Radio hams

I had no idea that standing and travelling waves was reserved for post doctorial studies in America, where offshore it is considered as an early part of the education curriculum. There are also physicists, consultants, sailors,naval instructors, NASA Reps cb ers and lecturers on this group argueing vehemently over the subject as if it is the cusp of modern day research. Each discipline having the benefit of being educated in such in a manner suitable for the class content. Considering the heated debate on mathematics on its misuse by a doctor working on space research at MIT I really should not be that surprised. It would appear that there is not a true foreign professor around to consult or to request some teachings from so this debate of several years could have closure. Reminds me of the 'O' ring debate in America where it was discovered for the first time in the western hemisphere that butile O rings had a low tensile strength, this found over some one's dead body. We desperately need more Indian techs to settle over here to help us out, and possibly one to join the group, instead of marvelling on the side lines at the goings on regarding the pursuit of knoweledge about radiation.
We have more than 500 permanent Indian and Asian technicians in my town hired by State Farm in a desperate effort to upgrade their computor comprehension and Bill Gates is also crying desperately for employees from offshore venues. Our hospitals would just rot if were

were not aided by the educated from the emerging countries who are leap frogging us in many ways. Caterpillar went to Northern England to staff their metal pattern shops. As for the rest they generated the 'Rust Belt' regions by sticking with what they had. Surely we can find just one that can inform the group about standing and travelling waves! Gentlemen and radio hams, you can join the group without leaving your countries to show of your education on this newsgroup. They need help over here.....desperately.

Good recovery.

But, of course, V(t) and I(t) are general functions
of time. In particular, the discusion was regarding
pulses.

Only when one constrains oneself to sinusoids and
chooses to use the complex exponential notation
is it necessary to use Re[].

But it was a good recovery.

Chris,
I am often reminded that as a mechanical engineer
which puts me lower than a sailor I should
stay out of electrical matters so on this one I am holding
back as my questions on the subject were answered to my
satisfaction. On the other hand Clark is asking lots of questions
as if he is the adjudicator of what is right and what is wrong.
Also Roy, who states reguarly that he is a antenna consultant no less
is having trouble as are the other instant experts. So Chris as a
newby on the newsgroup you are in excellent position to supply the
correct answers that all are so desparately looking for,
tho if you are an electrical engineer I have little hope for closure.

Comment #1: When you say radio hams remember that in the US the "ham" is neither professional nor an occupation. In fact, it is considered bad form for you to be discussing and attempting to gain information to enhance your commercial 'invention' if indeed you are applying for a commercial patent on your idea. You should define a clear separation between your amateur and commercial activities and this is something that frankly has been bothering me.

>
> I had no idea that standing and travelling waves was reserved for post
> doctorial studies in America, where offshore it is considered as an

Whomever said it was not taught here as an early part of the curriculum? I honestly think that you have an improper understanding of the standing wave and its equations.

> There are also physicists,
> consultants, sailors,naval instructors, NASA Reps cb ers and lecturers
> on this group argueing vehemently over the subject as if it is the
> cusp of modern day research.

Not really. We are discussing it as it relates to amateur radio antennas (that actually work). We are correcting each other as to how its measurements affect, for example, the phase delay in a coil of a bug-catcher antenna. We are far too low on the technical food to emulate you and relate to such grandiose ideas as solving the unified field theory or trying to explain the economics of global outsourcing where Bill Gates and others can hire 10 times the "engineers" at 1/2 the cost. Bill will get plenty of US technical labor at that point in time when americans are forced to accept the reality that they must accept pauper wages or do not work at all. This has NOTHING to do about differences in education. In fact, you will see many Indian students at your beloved MIT who are forced to repatriate to hteir home countries (although for me, I happen to find that going "home" in Wisconsin is a nice thing, not a bad thing) after receiving their diplomas. Bill Gates and IBM simply want them back and they will willingly return, given the chance at a green card or H1B visa, since receiving 30K per year in the US is far better than reciving 4K per year in India.

This has othing to do with a "hobby" or a "radio service" intended for use by "amateurs" who are paid nothing at all.

Upon reading this, my first question was 'what do O rings designed by American or Indian engineers have to do with ham radio?', Suddenly I realized that it involved the levitation of diagmagnetc O ring material where perhaps current might travel through the center ;-) Perhaps you could contact NASA, as a professional activity, and set them straight as to what to do. Just give them a clue; then they can hire their 30K/year Indian engineers to complete the solution.

Frankly I believe that order would be too tall for you. I really don't think you understand the equations but any mechancial engineer would have been

taught this phenomenon early in his curriculum. What happened? Did you forget? Has it been too many years? Did nature in her cruelty decide to file that information so far back in your memory banks that there is no hope for a simple recovery of said information?

> Gentlemen and radio hams, you can join the group without
> leaving your countries to show of your education on this newsgroup.
> They need help over here.....desperately.

Thus ends my participation in this troll thread.

Pulses can be analyzed as Fourier sinusoidal functions with multiple
frequencies. Point is that you could have saved a month of grief on
this newsgroup if you had initially said your power equation applied
only to real voltage and real current. If you had done that, nobody
would have argued with you.

Thanks to all for these helpful answers. The antenna looks like an 8" fiberglass CB antenna with the screw-in ferrule at the bottom. There is no direct connection to for a coax cable, nor was anything else included, just the fiberglass whip.

Bill Longyard

I am just a member of the WORLD wide web who has been viewing this
discussions of many thousands maybe tens of thousands of postings over
more than a decade. I am not sure if it is all a case of hitting Cecil
or that you cannot compete with his knoweledge. As for me I have also
been attacked for more than a dozen years because it is felt that my
ideas are all baloney. I share every thing I do with respect to ham
radio. I write up patents as a record of my work. How can I possibly
make money on my ideas when every body derides them as baloney without
providing a basis?
State Farm states that the talent is just not out there when the
subject comes up.
GE many years ago decided to get into the literal money side of
business and cut back on manufacturing e.t.c.Loads of engineers laid
off. About 80 at my plant went out the door leaving only six of us
engineers left.
If State Farm is correct then our teaching institutions are taking
money from students on the guise that a golden pot awaits. They
quickly find they have debts and nowhere to go.
As for hams on this newsgroup they costantly remind me of their former
employment to give credability to their statements when trying to down
size me.If you feel I am taking improper advantage of ham radio on a
commercial scale then talk to the FCC and also mention Roy by the way.
My ideas on waves may be way off but I am not really interested in
talking about them and probably have nothing to offer. When all of
this group challenged a well educated person on the validity of adding
a time varient to Gaussian law so it equates to Maxwells laws I was

shocked. That this group would fall over themselves denying the validity of the math expressed
changed me immensily as does this savaging of the question of standing waves.You don't have to make excuses to me why the standing wave can't be resolved as with the mathematics supplied from that member of MIT, This is viewed WORLD WIDE and those viewers are not stupid.
I know that my new antenna aproach is correct. You know that all that is new will be rejected.
So when it becomes recognised and sort for by offshore companies should I refuse them as an american when science outside of the academic circle is berated? I have shared everything and I mean everything, about by work with radio hams in the hope of bettering the hobby. To reject is their choice especially when you intimate that it doesn't work without reason. When this group requested a computor set up so a member could check it out on his own program. Yes, the data proved my work but what the hell, this group wanted to fight! Well I am still here even tho my country rejects the science supplied. So you can get back to your waves thread and continue to tell all of them where you are correct while everybody else is wrong. As David intimated the subject is good for quite a while yet, at least while Cecil is still alive. But unlike Cecil who lets insults slide by I think it is well past time to send some insults back
which those who insult consider shocking. I am very pleased that you have decided not to pursue this thread because the actions of the group speaks for themselves to the World
Changes need to be made in America, but without acceptance from american employers and the complacence of the population the future looks dire.As for me I have made my pile and feel good

> only to real voltage and real current. If you had done that, nobody
> would have argued with you.

An earlier post suggested that you "had got it", but these
last two posts leave me wondering.

P(t) = V(t) * I(t)
where V(t) and I(t) are functions describing the actual
measureable voltage and current at a point on the line.

Examples of V(t) would be
V(t) = 10
V(t) = A cos(wt + a)

These functions all yield real results since the voltage
measureable at a point on the line is a real function
of time.

When the latter example is written in complex exponential
form it becomes
V(t) = Re[A*e^j(wt+a)]

Re[] is not there because there is some imaginary part
to be ignored, but because this is how one writes the
function for V(t) in this notation.

Thus Re[V(t)] is non-sensical since the Re[] is already
in the expression describing the function.

My apologies for not detecting this subtle bit of
misleading thinking when I wrote my earlier reply.

...Keith

No John you are not a typical sample of this group. I have been on it
for over a decade
as have the two Richards and Roy. During that time we had a lot of
experts on hand that supplied info to the rest of us. But one by one
they all left because of personal attacks as the latest newcomers will
find to their cost. But I and Cecil and a couple of others are
standing our ground despite the reputation of this group. We are
interested in ham radio and ideas and do not subscribe to the idea
that all is known and if disputed must be crushed.
I have a small 160 metre antenna on top of my tower that is in
equilibrium,resonant and without the need for a ground. It is viewable
by anybody especially those with small gardens that are excluded from
that band. Why on earth would three guys try to suppress that fact?
What is it in there that they have a desire to supress? Would a full
size antenna small enough for a mobile without external loads or
ground requirements to get on 160 metres a real threat to ham radio?
John, you made Vincents antenna for yourself to obtain the facts. It
is not perfect but it is something new.You know Vincent was and is
under attack. The antenna
may not be perfect but some thing is new so hams ditch the baby with
the purifying water.

That was me. Forgive the sarcasm. Sometimes that doesn't come
across well in posting.

I'll be straightforward.

Your comment about Eznec as you quoted...

> The NEC program is just a computer model, for discussion purposes only.

End qoute

That statement is absolutely wrong.

I have designed antennas using the program. I have studied the presumed properties of these antennas. I have put these antennas together.

Upon testing and use of these antennas, they have worked in a manner consistent with the way the program predicted that they would.

Once you understand the difference between standing waves, (which has no real power itself but which stores the reactive VA power into that power which is is eventually dissipated in "radiation resitance" dissipating into free space as radiation power), and traveling waves, which do have real power that is also disspated into that same type of radiation power through the radiation resistance, an interesting question becomes "what is the nature of this so-called radiation resistance which dissipates the power of a forward wave or the stored power in a standing wave?". We feed power into the antenna as electric current and then it exits the antenna as radiation. Maxwell's equations (in spite of what art theorizes) says that the power has been converted to an EM wave. So, electric current, which is not an EM wave consisting of photons and propagating into space, is converted into a different form of radiation energy that IS an EM and does consist of phtons and waves. When this conversion occurs and energy is transmitted into free space, we attempt to quantify this net loss to our generator with familiar terms, i.e. current or voltage dissipated into "radiation resistance". However, we all know there is no actual physical component known as a radiation resistor. Conceptualizing how this power conversion works goes back to maxwell: "why" is there a time varying EM magnetic and electric field (external waves and photons) generated by the flow of current? Well, it could be described as nature's tendency to maintain equilibrium. If a change is made to a conductor by putting a current through it, nature "objects" and fights back by setting up an EM wave that tends to cancel out the incoming current pulse. But no matter what, I will always easily have enough energy in my forcing function (current or voltage) to overcome nature's objection and send a net outflow of energy occuring as radiation theoretically equal to what I inputted.

Art's unusual theories apparently have something to do with this same conversion of electric currents on the antenna to the radiated energy that propagates through space. Art believes he has made discoveries that augment the maxwell equations and solved the nystery as to how this power is converted from amps to radiation. He essentially takes advantage of the fact

that scientists and hobbyists (at least on THIS board) have not done a good job conceptualizing what actually happens during the process of converting electric current from a generator to a radiated wave into free space. Our rather feeble invention of the radiation "resistor" helps us in the design of our antennas but it is not conceptually correct; a resistor is obviously dissipated as heat, not radiation (other than infrared heat). So how, physically does amps/volts in a conductor dissipates as radiation? That is a good question. And Art will give you a very UNacceptable answer to that question. No, the current particles do not fall out of the ends of the antenna and get levitated as galactic particles; this is the sort of thing, frankly, that you might hear from children. However, Arthur has been very persistent and I believe that over time persistance CAN overcome handicaps in both inteligence and education, at least on rare occaisions so I have tried to cooperate with Mr. Art up to now. That is, until I read into the poor attitude and tone of his posings on this thread "Education". Indeed, he attacks even people such as myself who have attempted to encourage him. Now I see him for what he is...a simple crank of no relevance to the the scientific community out of his own choosing. He has no "small' 160m antenna on his tower (so he is a fibber), he doesn't know the difference between a standing wave and a traveling wave, is not familair with present models and their difficulties. If point zero is at the beginning, Mr. art is at -7 and he refuses to learn any tools that he needs to advance. I too would like a better conceptualization of why/what and how maxwells EM fields work and how the power conversion physically occurs on an antenna but for now I am stuck, along with everyone else, using the radiation resistance model. For all of its conceptual drawbacks, it works just fine mathematically. One key to better understanding (my opinion only) may be in more recent exotic physics models such as dark matter interactions with EM fields but that is way beyond any understanding I have at this point; that is why I previously took an interest in art's theory but which eventually went nowhere (too bad). I don't criticize him for that; he just needs to sharpen his tools a bit and take a completely different path if he is to succeed (but I predict he will not). Levitation of galactic particles in my opinion is not the path to success.

Apparently, the measurable *instantaneous* voltage and current. We could have avoided a lot of wasted time if you had stated those conditions a month ago. None of my references contain that equation.

Thanks Mike, such information makes me interested in trying it out and sorry on my part too for any miscommunication and statements about 11m. I am from a generation where computer models had many limitations but I am now convinced that EZNEC has probably long overcome the weaknesses of the past. I should not make assumptions without trying it out first; most likely my initial statements are wrong but I doubt I mislead any of the regular participants on this ng. As for the newbies, you would be better off assuming that my off handed intial comments criticizing EZNEC were WRONG. Sorry about that.

> on his tower (so he is a fibber),

I interupt your post at this point only since you are expressing your
views as in free speech
but to be a fibber, a lier in other words is a deliberate untruth. At
the moment I do not have the smallest antenna for 160M on my tower
since the radiator is around 18 foot long and tipped at an angle to
reflect what the computer states. I suppose I will have to make one
that will fit into a 1 foot cubed carton to satisfy the term small. We
have plenty of hams in this community plus repeaters so you can come
yourself or ask a surragate to inspect on your behalf. It is a fold
over tower so close examination is possible and I have all the
necessary equipment to measure impedance or what have you. I also have
on hand a loop style antenna for 20 M made on a hoola hoop, so I could
convert that to 160M. On top of thatJohn has just rigged up Vincent's
antenna that every body decries.
If he were willing I could describe modifications for the same antenna
constructed for a smaller size plus without the need for ground to
avoid the comments applied to Vincents antenna . I have never met John
but I believe him to be honest
So I will supply him the details if he wants them and he can report
results to you without pre inspection from myself. On the other hand I
can build a small 160 M antenna and send it to hime by post office
mail which he can play, with and report upon.
Disagreement and suppression is one thing but a lier I am not! Either
way I will now make a 160M small antenna incase it becomes desired.
Yes I am very hurt by this barb and will work hard in full filling my
side of what I have discussed. It may finish up a bit bigger than a

foot since I have no idea how small it can be made but it will be
small for shipping via the post office.It will be made of#22 wire so
that it can also be tested for heat resistance, the bain of the EH
antenna as well as Vincent's and many others. I haven't tested for
that but see no problems as #22 should be able to handle normal use

Hi Derek,

Actually, having a small 160m antenna is the "one hell of a statement".

That being the case, the burden is on art to back it up in the positive.

He will not.

Nobody can prove a negative; it is up to art prove the positive.

Sorry but your assumption cannot possibly be correct since it is impossible
to prove a negative.

That's great, Art. How's it working out for you? Did you work J5C over the past couple of nights? Did you snag G3JMJ's loud signal this evening?

I can load my 6m beam on 160m, but it doesn't work well at all. I use a slightly long inverted L with a series vacuum variable and nearly 6,000 feet of buried radials. There's a three inch short, tapped coil to ground at the feed point in order to match the antenna to the RG-213 I feed it with. The antenna isn't small and it isn't elegant.

I'm willing to listen to your ideas about how I can equal the signal from that inverted L by using a much smaller antenna. Why don't you post information on such a creation?

You made a positive statement, You called Art a "liar" that is a
big difference from saying you disagree with Art's claim that he can
build a small 160m antenna, if you can't back your statement up Art
deserves an apology.

I am curious. What other interpretation than 'voltage as a
function of time' did you have for "V(t)"?

And, of course, when you plug any particular time into a
function describing xxxx as a function of time, you get
the value of xxxx at that time; the instantaneous value
of xxxx.

Or is there another possible interpretation?

> I am curious. What other interpretation than 'voltage as a
> function of time' did you have for "V(t)"?

Strange question. My interpretation is not the "other interpretation".
My interpretation is the (apparently) standard one from "Fields and
Waves", by Ramo&Whinnery - begin quote:

V(t) = Re[Vm*e^jwt]

Because of the inconvenience of this notation, it is usually not
written explicitly but is understood. - end quote

When you used the term, "V(t)", I understood it to represent the
Ramo&Whinnery definition applying to exponential notation. Your
interpretation is the one that differs from that definition. What
other interpretation than the Ramo&Whinnery equation do *YOU* have for
V(t)?

> Or is there another possible interpretation?

Apparently there is and you can prove it by providing a reference that
extends V(t) in the Ramo&Whinnery definition above to something other
than exponential notation. I am not doubting your word, just (pretty
please) asking again for a reference that agrees with your statement
that V(t) is used for something else.

If "V(t)" is commonly used outside of the Ramo&Whinnery definition
above, I apologize for being confused by the notation being used.

I absolutely did not! Show my a quote where I used thre word liar. I called
him a fibber. Big difference. A fibber might actually have something like a
160m antenna, true, but as for 'small' that would be his exagerration based
on his literary license with words. He later said it was 16 feet in length.
That is not "small". With a large loading coil I could build a 16 foot very
inefficient 160m antenna but it would be a fib to say it was 'small' without
also stating the length. The term 'liar' is your own term that you made up.
apparently.

that is a
> big difference from saying you disagree with Art's claim that he can

Sure, IF I has used the term liar but that statement is in itself a lie.

> If "V(t)" is commonly used outside of the Ramo&Whinnery definition
> above, I apologize for being confused by the notation being used.

Apology accepted. As a cautionary note....
It is unwise to take the notation used in one text and blindly
substitute into another, especially when the text is deriving
for a specific case.

The IEEE dictionary (see 'instantaneous power') starts with
p = ei
and then goes on to derive the special case for sinusoids.

Desoer and Kuh, "Basic Circuit Theory", start with
p(t) = v(t)i(t)
then derive the special case for sinusoids by substituting
v(t) = Vm * cos(wt+a) = Re[Vm * e^ja * e^jwt] {taking some liberties
to make it ascii}
Note that Re[] is only needed when using the exponential form
and not the trigonometric form.

And, from your post, it appears that Ramo and Whinnery start with
W(t) = V(t) I(t)
and do the derivation for the special case of sinusoids by
substituting
V(t) = Re[Vm*e^j(wt+A1)]

These are all equivalent derivations using different notations.

A key point is that they all start with "instanteous power
being equal to instantaneous voltage times instantaneous current"
as the general case and derive the special case by appropriate
substitution.

And a second key point is that Re[] is not needed in the general
expression for power, (choose the form you like)
p = ei
p(t) = v(t) i(t)
P(t) = V(t) I(t)
, because it is already in the expressions for voltage and current
when the exponential form is used.

I think 50%+ of my earnings go to gov't. I don't think "government
would be BUYING me anything"--we would be purchasing it for ourselves.

Gasoline tax, property tax, transportation tax, booze tax, tobacco tax,
federal excise--phone tax, cell phone tax, etc., etc.

Reader Digest used to do an article once a year which showed how long a
person must work just to pay his her taxes--last I seen (years ago) it
was past April headed for June; anyone read that article lately?

The government is "of the people, by the people and for the people", if
you find anything different--there are already dark forces in the
government which need removed ... while communism is certainly something
we need fear--we should first correct the current clear and present
danger ...

Regards,
JS

This newsgroup is the source of some of the best and knowledgeable answers I have found on the net.

Unfortunately, it now seems to suffer the same malignant plague as many others--disagreements decaying into personal insults.

There have been disagreements over radio/antenna theory for over a century, but look at what progress has been made in spite of the differing opinions! If we base all of our current knowledge on what is written in a book, then we are at a stalemate and RF progress is doomed. Remember that the Earth was flat for millenia! Yes, let's disagree--it's healthy as long as it is done with respect.

So what path do you do you all REALLY want to follow? Loops, Yagis and feedlines or Heraldo, Maury and Jerry Springer? (Rhetorical question)

73 to all.

If a efficient antenna is less than 20 feet long without any loading
and without a ground plane or matching systemsis not considered
"small" for 160 metres then pray tell me what is considered "small"
and I will take mine down and replace it with a smaller one.
In the mean time, I will accept that I am a liar, because my
definition of "small" does not meet your personal requirements
and all that's new on antennas must be rejected by slander
if necessary. As a newby you sure lined up quickly with the habits
of the founders of this group!

sigh... All too true.

I find my filters are now killing 70-90% of all new postings and
followups.

I fear some - if not many - of the folks that were "... the source of
some of the best and knowledgeable answers ..." may have abandoned this ng.

Notice how fast this thread degenerates into name-calling and
cute-only-in-the-posters-own-mind one-liner insults....

I am a retiree like many on this group living in Perth Australia,
who after many years of following this group has a great belief that
Art can do as he claims.
I am also a great believer in fair play, and calling someone a
fibber (liar) on open message without proof is not fair play in my
book.

Derek

You may have a great faith in art but not quite enough to say so publically, do you? It is easy to be an art unwin groupie (no...NOT so easy for most), taking an insane position under the cloak of anonymity. For that reason, I really think you have reservations. If you really believed in antennas that shot particles out the ends, you would say so in the open! I googled your userid and I see that you exclusively post only on rraa and only as a cheerleader for arts theories on rraa. I have not seen one post of your's that had any technical content. Fibber? You saw he defined is "small" antenna at 18 feet; that's not small; anybody could load a stinger that long with a coil and transmit at 160m so you're damn right it was a "fib". See ya Derek, knowing that you have nothing technical to offer and that I don't need to be bothered all the time by the unwin groupie cheerleader; plonk.

Arthur don't be so silly. As a fellow over-the-edge old fart
mechanical engineer you've obviously missed some some fundamentals.

Back in the day the IEEE and the ASME came to an agreement: They
wouldn't fiddle with Mohr's Circles if we didn't fiddle with
electromagnetic wave mechanics. You're in violation Arthur so so knock
it off.

How many countries do you have confirmed on 160?

They are rated the top two threads at the present time (yesterday)
I can't remember the titles or every thing that was written but as the
top articles of interest I don't think you can consider it as looking
for a needle.

You say I am taking an insane position. You also say I have
reservations.
You know my name is Derek and that I live in Australia.
Art states he has an antenna for 160m on the top of his tower,I have
not seen it neither have you.
Over the years Art has stated many facts about this antenna.It is in
equilibrium without loading which also means it does not require a
ground plane ie direct connection to the feed line.
I also assume that impedance is termed as an acceptable level with a
suitable SWR so it can be driven,If it is on top of the tower with no
other support "most" would consider that small for 160m.
Now you can call him a liar, and I believe that he is not.!
So..... I am willing to raise the money for a wager based on the
above where you may place other conditions in this quest to determine
if Art is a liar or not.
You can also choose the judge, and who holds the money since I am
in Australia.
If we come to an agreement on terms I am willing to put down up to
$5000US.

All of the above is subject to Arts agreement for access to his
antenna
of course.

Derek

I am not in violation in my opinion. My theory may not be "exactly" correct
as I have no way of looking at particles. But if you Google every little bit, line by line it has enough agreed tangibles that it can be taken as serious. You yourself know that I have been sharing the details for a very, very long time. I also have shared everything and described everything, nothing has been hidden and all explained several times
Nobody has faulted anything one little bit! Pretty much all has been the
slandering of me. I really do not understand that if this is a newsgroup on antennas
why those knoweledgable in the state of the art instead of getting angry with me doesn't debate it point by point where an error provides a stop to the debate.
Ofcourse 'error' means so many different things with this group I don't see a long thread.
I certainly do not have the patience to post thousands of times as Cecil is able so I should easily be forces to go away as others have done. Well, if you try very hard that I cannot take anymore. When you have received an education one must always take advantage of it by pursuit of the truth regardless of the regimen. I cannot see why I should be expelled from intruding into physics by those you insist that all is known about antennas otherwise you are a heritic.

I have never made a list of countries worked. Never had reason to do
it
I have only entered one "competition" when I was challenged to compete
in being 1 of the three
of the 9th group to have a contact with some station. I was never
given any warning of the when and where but I can say the noise was
horrendous. Why people subject themselves to that I do not know. On
the other side I generally use ham radio to keep in touch with my
friends in the UK which now I do by phone.Why all these questions? Is
another assault in the offing
from a college lecturer?

I think you'll like it. There are some things that it won't do, but I
think that on the whole, it is pretty capable.

It took me from absolutely clueless to neophyte pretty quickly. I
can't keep up when the gurus here start badgering each other, but I can
put something up, and have some understanding about what I'm doing.

Well put, Daniel. One of the biggest difficulties I have with Art's
theories is that I can't get my head wrapped around them. I know he
unfortunately has a few physical challenges that make his postings a
little difficult to go through at times, so I re-read them often to see
if I can glean something out of them.

But whereas I have great difficulty with some folks posts. I understand
everything you wrote.

On what do you base that belief? Many of us have asked Art for some input on building one of his antennas, and we don't get anything. Heck, I'd even enjoy a picture, or a visit to the QTH to see something being used. But we get nothing. I'm not a fan of faith based engineering.

Derek - placing of wagers is not an argument. I haven't partipated in
calling Art anything. It isn't a difficult thing to get a picture of this
antenna, I would even offer to post it on line.

It's simple really. Extraordinary claims require extraordinary proof.
show us the antennas, let us build them and test them. Let us compare them
to other antennas.

I make all my antennas. I don't have to buy them.
Also, where do you get the idea that gambling comes
into play here?
I don't live in Vegas, and 8 liners are illegal here.
When I hear of gaussian jibber jabber, I think of this..
http://home.comcast.net/~nm5k/gauss.jpg
In fact, I'm starting to wonder if you are not related
to this gentleman. Small size means nothing if
most of the power turns to heat. This even applies
to aliens.

Let's not. I'm not a gambling man either. I will say that a credible theory
that was repeatable would not require a Las Vegas style wager to demonstrate
the odds of its success.

Once again, what is the diameter of your 18 foot 160m antenna?

I know what others have said, Art. I asked if you'd share your ideas.
You have often dealt in non-specifics. I'd like to see how you think a
small antenna can be made to equal the performance of the full-sized
inverted L.

No.
The two hottest is what I was pointing to when I responded to the
other person. One is called 'How radiation is created' or something
like that. The other is the assistance I gave on a "homebrew antenna".
The first thread is what I initiated with the call sign KB9MZ. Both
still remain at the top of the hottest list and probably will still be
for the next couple of days. After which they may well stay on that
list anyway.

817. folding a dipole in half

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-14 12:49:14 UTC
From: gsm@mendelson.com
Message-ID: <slrnfommgr.i89.gsm@cable.mendelson.com>
Source record: 29583

I have a very short space where I need to put up a temporary antenna.
It has to be rolled out during the day and rolled up and hidden at night.

20m would be a good band for me to use, and it will just about fit, so
I was thinking of a 1/4 wavelength radiator with a 1/4 wavelength
counterpoise made out of wire.

Since I have lots of 300 Ohm twinlead just sitting around, I could
make the radiator out of it. I understand that if I were to short both
ends and center feed it, it would be a standard 300 ohm folded dipole.

I think if I were to short the ends and end feed it, it would be a
eaquivalent to a wide(er) 1/4 wavelength end fed antenna and still
need a counterpoise.

What would happen if I were to end feed it as if it were two seperate
wires, either with a balun or without? Would it work? What is this called?

Thanks in advance,

Geoff.

818. Airport Tower Comms, and My Receiving Antenna Orientation ?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-14 13:47:31 UTC
From: Robert11 <rgsros@notme.com>
Message-ID: <y4adnTN2uMlz-hbanZ2dnUVZ_oCvnZ2d@comcast.com>
Source record: 29584

Hello,

Not an antenna expert, so thought I'd post my questions here, for all you theorists.
Would appreciate any thoughts on the following, as it really confuses me.

Have a new handheld scanner; GRE 500 model.
Has a rubber duckie for its antenna, which is pretty typical for these kind of scanners, of course.

Tried listening to an airport control tower (118.5 MHz AM), about 5 miles from the house.

Here's what I found playing around.

When the unit is held normally, that is with the antenna vertical, the airport comms from the tower were really poor.
Lots of static and noise.

But, much better when held horizontally.
a. Any idea why ?

I would have thought that their antennas would be polarized vertically to communicate with planes.

b. any idea how their tower antennas are likely polarized (if at all) ?

c. and this one really confuses me.

The best reception, by far, is if I point the antenna vertically, but DOWNWARD ! Big difference from vertically up.

Wouldn't vertically up, and vertically down be identical and symmetrically the same re polarization, reception, etc. ?

Thanks,
Bob

If I understand what you are suggesting it would be a shorted transmission line, not an antenna. I would look at an end feed half wave antenna, like a zep or the ones from PAR electronics. I've homebrewed them myself and they do work.

"I think if I were to short both ends and center feed it, it would be an equivalent to a wid(er) 1/4 wavelength end fed antenna and will still need a counterpoise."

No counterpoise needed. Its called a "folded quarter wave dipole". Its first resonance is due to its 1/2-wave circumference. Its input resistance is not 300 ohms but 600 ohms. Its gain is 0,5 dB less than the 1/2-wave dipole. This information is from "TV and Other Receiving Antennas" by Arnold B. Bailey.

You might want to feed it with 450 ohm ladder line.

Best regards, Richard H. Harrison. KB5WZI

Hello Rob,

Did you do the tests indoor, or very close to objects?

As far as I know, VHF AIR comms are vertically polarized (ground
station).

Due to reflection and refraction, polarization may change and the field will no longer be uniform. So the strength and polarization varies with position of the antenna. This is also valid for various sources of interference.

Your rubber duckie will be part of the antenna; your hand, arm and body will be the rest of it. Your hand serves as ground / opposite pole for the antenna. Probably you will find more spots where you have better reception (or even no reception).

I live about 16nm SE of EHAM (Schiphol Amsterdam, Netherlands), flat terrain profile, very thick full wave dipole, 30 ft height above average terrain. Signals from ground control are strong; signals from airplanes at airport are reasonable. I use a 3 pole preselector to attenuate broadcast signals. When you are going to use a larger antenna, you may get intermodulation problems also.

Best regards,

Wim

Hi Geoff,

I presume by this you mean you have enough, total length, to create a halfwave dipole for 20M in the conventional sense.

>Since I have lots of 300 Ohm twinlead just sitting around, I could
>make the radiator out of it. I understand that if I were to short both

To some degree, but that will bring nothing to your advantage.

>I think if I were to short the ends and end feed it, it would be a
>eaquivalent to a wide(er) 1/4 wavelength end fed antenna and still

Yes, and it brings into doubt my presumption above. It would inform us all if you gave us the dimensions of your available space.

>What would happen if I were to end feed it as if it were two seperate
>wires, either with a balun or without? Would it work? What is this called?

An aircooled resistor.

It isn`t. Just as elsewhere, electromagnetism and wave motion are covered in freshman physics. Anything needed beyond simple algebra is covered in the physics course itself. It includes the relationship of classical physics to modern physics, emphasizing conservation laws, concepts of waves, fields, and particles.

Best regards, Richard Harrison, KB5WZI

Cecil,

That is certainly an interesting characterization. Is your position that anyone who disagrees with you must be a spoiled brat? And who provided the ad hominem attack in this thread?

You are of course able to believe anything you wish. However, all of your handwaving explanations about reflections and phase shifts and phasors will not be found in ordinary discussions about the Poynting vector. Your "simple math" proves nothing at all, not even close. It is not reasonable to substitute current and voltage for E-field and H-field when considering the Poynting vector. The vector nature of the fields is essential to properly determine the cross product. Go take a look at the actual field configurations for a TEM wave, which includes standing waves, and report back to us.

Everything I said in my previous post is exactly correct.

Cecil,

You keep ignoring the "sloshing" explanation. Actually, you did not totally ignore it; you did indeed criticize the choice of the descriptive word "sloshing".

The standing wave envelope may be stationary, but the fields are not. There is no conflict with your photonic requirements.

Since this discussion about fields and waves seems to annoy some of the "good buddy" crowd around here, I will quit now and let you win by default.

If you really cared about the newsgroups, bozo, you wouldn't be posting
off topic junk to them.

This is no better than when you posted about dog food to rec.radio.shortwave,
and then turned around and changed your user name so we'd think you
were someone else.

Just because idiots abuse the newsgroups is not a reason for other idiots
to follow.

You didn't need to add anything to this thread, and keep it off topic.

You certainly didn't need to change the subject header so it looks
like you are starting another thread, a completely off topic thread to boot.

YOu could also consider that some idiot cross-posted this thread in the
first place, which is always a good reason for off-topic junk to start
up, and by adding to that mess, you just continue it all. Usually, if it's
cross-posted, you shouldn't reply (since virtually no cross-posting serves
a purpose, it is indeed the mark of someone too lazy to find the appropraite
place to post).

Finally, the only way you could be dazzled by the idea of someone making
tubes at home is because you lack depth beyond your ability to post links.
YOu saw it posted somewhere else, I don't for a minute believe you found
it through hard work on your own behalf, and like other people decided
it was "too good" to not post in yet another newsgroup, just like others
before you posted to other newsgroups where you found it.

Come up with something original, like the exact date of that 1964 article
in QST (or perhaps it was CW) where there was an article about an Argentinian
who made tubes at home. Because then you'd prove this isn't a sudden and
new thing, despite the internet wrapptings, and you'd actually add something
to the discussion, beyond an ability to use search engines.

Or spend some time in a used book store, finding and then buying the books that might be relevant to the discussion, and then start making the tubes yourself.

Hi Geoff,

Put up 3 to 5 sections of twinlead (with the wires shorted at both
ends) on each side, fanned out at the far ends across 3 to 5 feet
(looks like a bowtie). Feed at the apex of each triangular half, that
meet in the middle. Choke the cable feed.

2:1 SWR bandwidth should be at least 1 MHz wide.

> When the unit is held normally, that is with the antenna vertical, the
> airport comms from the tower were really poor.
> Lots of static and noise.
>
> But, much better when held horizontally.
> a. Any idea why ?

There are 10001 resons, but airfield communications ARE vertically polarised. They tend to use discone antennas for VHF and the "biconical monopole" for UHF. However, they are designed to broadcast to aircraft, which do not sit so close to the ground and so far away. There is likely to be an array of different antenna at the control tower and/or transmitter site, all of which could slightly affect that which you are receiving.

The "rubber duck" antenna is NOT a 1/4-wave antenna at all. It is in fact a 3/4-wave antenna all coilled up, which gives a radiation pattern a little close to the fictitious "isotropic" antenna. People playing with rubber duck antennas on handheld gear rarely hold the things vertical, so the 3/4-wave gives a more uniform radiation in all directions - especially slightly up and down: more like a cylinder with a hole down the middle, than a donut. Another point is that the impedance of the 3/4-wave is more constant when your hands and head are close to the thing, but that is irrelevant for your application.

Buildings tend to use metal structures, fittings, and wiring, all of which affect the passage of radio signals through them, especially at VHF. I have succesfully use existing mains conduit in the ceiling of a rented appartment as an antenna, by mutual coupling of feed and resonant "current breaks".

Reflections from other buildings can also interract with the signal you receive. You may think that you predominantly receive the main direct path, but you would be surprised how often you are receiving reflections from other sources. Most GSM and all later generation of cellular phone base stations use polarisation diversity. That is one array of antennas 45-degrees to the left, and another array leaning to the right. All this is necessary because reflections and movements change polarisation.

Q1: Are you sure that the antenna is vertically polarised?
To be vertically polarised then the end bit should be higher than the bottom bit, and pointing at the sky. (Suoopid suggestion, I know, but you never know :-)

Q2: Is the signal very strong? If weak then it could be arriving from any source. If you building is shielding your then you may be relying upon reflections from the bus park, aluminized billboard, power pylon, or the neighbours TV antenna, for reception.

If you really want to receive these stations then use a simple antenna outside, in a controlled environment, without any unknown influences. Such an antenna need not be very complicated, in fact it could be built in a few minutes using a bit of wire and a broom handle.

This link even does all the simple antenna calculations for you, for any frequency you want.
http://web.telia.com/~u85920178/antennas/vpole0.htm

If you want to receive a specific band with decent sensitivity (weak signas) then this link will give you some idea.
http://web.telia.com/~u85920178/antennas/6dbvhf0.htm

If you think that you have a weak signal, then see why at:

> 20m would be a good band for me to use, and it will just about fit, so
> I was thinking of a 1/4 wavelength radiator with a 1/4 wavelength

You can easily make antennas that are hidden. For example, get some of that aluminium tape they used on windows, then use it to make a loop on a large window. The alarm tapes also have contact pads that you can use to make contacts with them to feed the antenna. Such an antenna will work well for transmitting and receiving. You can change the direction by opening the window.

You could fasten the antenna to a packinmg crate lid, or even use the metal band around the crate, as I did. Hang it on the wall and put a dartboard on the other side. When finished just turn it over, or even leave it permamently hidden behind the dartboard. Put a lamp over the board to excuse the cable. http://web.telia.com/~u85920178/antennas/crate.htm

You could fix the aluminum tape to a carpet, then roll it up when finished.

Do you have the capability of adding a new plastic drainpipe? Looks good from outside, but can hide an antenna inside ;-)

If you are having trouble with neighbours, then make a wooden antenna using brush-handles, or even a fishing pole. Let the neighbours see it and make a fool of themselves when they accuse you of disturbance to the TV sets. Then you can use the real antenna another day without fear. ;-)

The trouble with having a "heckler" out there responding with megga-sarcasm and ridicule is that one feels duty bound to respond. DONT. Let stupic and non-constructive postings go unanswered, otherwise the escalate.

837. Solar cycle and radiation

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-14 17:24:07 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1299670f-4d6e-46dc-8741-5bbaf27c5ad3@q39g2000hsf.googlegroups.com>
Source record: 29453

The sun like earth has its own magnetic field.
However unlike earth the poles on the sun have a cycle of 22 years
where its magnetic pole turns around in a complete circle!
So every 11 years the poles change places and the magnetic
field gets stronger and then weaker.
This magnetic field somewhat inhibits the release of solar dust
that finds it way to earth. On the reverse side when the poles
turn the magnetic field weakens and the dust arriving into the earths
atmoshere increases a lot. This dust by the way is many times smaller
than the diameter of a human hair but when the system becomes
dense with these particles they look like a cloud as they reflect
light.
The Milky Way that one sees in the sky is a sample of such.
So it should be seen that dust arrival from the sun coincides with
radiation activities on earth. This dust is seen as inactive
particles
that mimic a decayed electron which atoms will reject from their orbit
any additional electrons which if accepted would destroy the
equilibrium
of which the atom is a part. Fortunately some materials will accept
the presence of these particals but only in a rest position and not
as part of the
atomic make up of the material. These materials are called
diamagnetic.
They do have electrical properties but do not retain magnetic
properties.
They can produce a magnetic field as a result of current flow which
happens
to be very weak as well as the magnetic lines created being at right
angles
to the axis of current flow. This very weak field can creat a
rejective field to
like materials where because of the proximity effect wwhich can give
what appears
to be a negative gravity effect on like particles. This effect has
been shown
to be effective on frogs no less but in general because of its weak
field its rejection
of solar inate particles is not visible to the eye. So it turns out
that when
earth suffers a increase in solar dust from the sun's solar position
it coinsides with
what ham radio refers to as a suitable DX period for
propagation.together

with a weakening of the magnetic field of the sun itself, because of the cyclic
rotation of it's magnetic poles.
The weakening of the magnetic field of the sun can be seen in action when
a eclipse occures where the rotational momement of pendulums, that occurs
with the reciprocative backwards and forwards movement, takes on a sudden
change in velocity because of the suns reduced gravitational affect on earth
that disturbes our equilibrium. This disturbance calms down as the sun
reveals itself such that equilibrium on earth is returned.
So that is what we can expect to be happening the next time we get on our
transmitters so we may talk to the World
Art Unwin KB9MZ...XG

Hi Harry,

Great explanations. Thank you.

I will try to build your suggested antenna first chance I get. Will let you know how it works out.
BTW: is this what's (also) called a "J Pole" ?

Should it be pointed in any specific manner toward the source of what you are trying to receive ?
e.g.: should a plane formed from the short & long lengths be pointed to the source ?

Q1: I have no idea how it's constructed, but what I describe as vertical, the "tube" of the antenna is true up-down vertical.

Q2: Signal is "fairly" strong; it's only the noise that makes it hard to listen to when held vertically in the normal manner. Much better horizontally, and vertically downward, like I mentioned.

All my listening is indoors; perhaps as you mentioned this accounts for the S/N being better horizontally and vertically downward due to reflections, etc. ?

Thanks again; appreciate your time and advice very much,

Bob

Look up the word "slosh" in the dictionary, Gene. It is impossible for
EM energy to "slosh". While you are at it, you might as well assert
that photons smell bad.

EM (photonic) waves do NOT change direction unless a change in medium
is encountered. "Sloshing" requires a change in direction in the
complete absence of a medium change. It is a very ignorant, impossible
concept.

> The standing wave envelope may be stationary, but the fields are not.

There is no net energy movement in the kx direction as evidenced by
the equation: cos(kx)*cos(wt). All the energy movement is between the
E-field and H-field at any fixed point along the wire.

> There is no conflict with your photonic requirements.

Of course there is and I proved it with math. If you want to prove me
wrong, prove my math wrong. Good luck on that one.

> Since this discussion about fields and waves seems to annoy some of the
> "good buddy" crowd around here, I will quit now and let you win by default.

Translation: I have discovered my error. The standing-wave E-field and
H-field really are either 0 or 180 degrees apart. Drawing those fields
on paper and superposing them proves it.

> actual field configurations for a TEM wave, which includes standing
> waves, and report back to us.

That's what I did already, Gene. You should take your own advice. It's
a little harder to visualize than voltage and current but follows
exactly the same concepts plus the right hand rule. Let's take two
equal coherent TEM plane waves forming standing waves in free space as
described by Hecht in "Optics". At one point the forward wave E-field
is at 135 degrees which puts the H-field at -135 degrees. The
reflected wave E-field is at 45 degrees which puts the H-field at -45
degrees.

Efor at 135 deg + Eref at 45 deg = |Efor|+|Eref| at 90 degrees

Hfor at -135 deg + Href at -45 deg = |Hfor|+|Href| at - 90 degrees

For standing waves, the H-field is 180 degrees offset from the E-
field. The power in the standing wave is ExH = E*H*sin(180) = ZERO.
Your assertion that the E-field and H-field are 90 degrees apart for
standing waves is simply FALSE! Please prove fact of physics that for
yourself.

Standing waves do not meet the requirements for an EM wave! Hecht was
right about that.

Feel free to do something besides wave your hands, mount ad hominem
attacks, and engage in obfuscation.

Air or Ground UHF and VHF antennas are typically center fed vertical
dipoles. The radiator is a fairly thick piece of Aluminum tubing to make it
broadbanded. The coax runs up thru the bottom section and it connects to
both halves of the antenna in the middle. The antenna is housed in a
styrofoam filled fiberglass tube. The coax connecting the feedpoint of the
antenna to the connector at the base of the antenna has several ferrite
beads on it used for decoupling. Disc-cone antennas used to be popular for
the UHF frequencies but have pretty much seen their day.

As you say, the energy moves between the E-field and the H-field,
but the locations of maximum energy along the line for each of these
fields is different, so the energy changes position on the line with
each cycle. The energy at any point on the line is not constant.

E-field energy will peak at the voltage maximums.
H-field energy will peak at the current maximums.
These are at different places (90 degrees apart).
So energy does move within the line, though no energy crosses a point
where the voltage or current is always 0.

http://www.eznec.com/misc/rraa/TLVis1.exe Demo #2 is a simulation that
helps visualize this change in the location of the energy.

Are you sure that it is noise, is there some speech or music in the
"noise"? It could be an intermodulation product or just overload to
your receiver from a local FM broadcast station. See what happens
when you listen outside. when it is interference from your own
domestic equipment, the level should drop when outside your house.
Many so called "wide band receivers" give problems when used with a
good outdoor antenna.

Hi! I've been wanting to upgrade my old Zmatch ATU which is 30 years old
for a while but although I've come across several designs, both one and
2 coils I cannot find the actual inductance values required.
I seem to remember an article in a magazine some years ago that had them
but I haven't been able to locate it so far.
I have some very nice Silver plated coil stock that I would like to use
but as I have determined for myself the value of the coil is critical as
the network doesn't like the tuning position for any 2 bands to coincide.
Failing the use of an air cored coil I might try a Toroid, but The coil
stock is in my hands right now. Any help greatly appreciated!

Hi, Cliff.
Are you sure about the age? I think I got mine about 1970 and it was
used then! I used it for years running about 100 watts and a dipole
fed with ladder line. Now it's just resting in the loft.

What are you wanting to upgrade? The capacitors won't take the voltage
of much higher power.

Can you measure the minimum and maximum capacitance? If so, and you
already know the frequency range, then you can compute the inductance
or read it off a chart. I am at work, so can't look at the manual.

In my experience this is really true, in many cases. Although I have a degree, I am retired from one position, still working in another (for a few years perhaps) and I am *not* encouraging my college bound son not to get a degree in engineering. It is not often that a BSEE or BSME ends up in a job that satisfactorily utilizes the knowledge he/she is taught. In Asia, to which these degree'd (and non-degree'd) jobs are moving anyhow, they are educated at schools in China that do not (and could not) meet degree accreditation by US standards, yet they are sufficient for computer design "engineer" positions. Where I have seen a degree education make a difference is in the field of analog design for medical applications but even there, once in a whiile you would find a whiz with no degree and design circles around the degree'd engineer. Some people seem to just have it, some don't. I want my son to go into bio-med (or maybe just "med") and stay away from this godforsaken field that the BSEE is overqualified for the (digital design) and overpopulated, for the number of jobs available. However, it does help enhance a fine hobby when you retire!

I can understand no energy crossing a zero current point, but how do you justify no energy crossing a zero voltage point when current IS observed? Current is defined as movement of charges, and charges have energy by definition (how can they be charges without energy?).

Another point, the current is observed to change directions during the cycles, polarity also changes on each side of the zero voltage point. Where might the polarized energy come from if it does not cross the zero voltage point?

I can kinda see how like charges could repell so that waves of like polarity might "bounce" but I can't see how waves of opposite polarity might "bounce". If waves of opposite polarity "bounced", why would the polarity change during the cycle on each side of the "bounce" point?

To me, it is much more rewarding to work with traveling waves that pass through one another, interacting to create standing waves.

Would it help your visualization process to observe that when two waves of SAME POLARITY but traveling in opposite directions cross, the currents accompaning the waves are moving in opposite directions both before and after crossing? When two waves of OPPOSITE POLARITY but traveling in opposite directions cross, the currents are moving in the same direction both before and after crossing.

If we were talking about water, water behind a dam is like voltage, with the height of the water the potential energy, measured in head (feet), or PSI if measured at the bottom of the dam. A pipe to the bottom of the dam will squirt water at a high velocity but no head or PSI. The potential energy of the water behind the dam has been converted to kinetic energy measued in velocity of a moving mass. The moving water can be stopped, and if carefully done, the static head reached by stopping the water will nearly reach the original water level behind the dam. It would reach the same level if it were not for friction losses. Electrical current is something like that moving water.

Cecil,

Enjoy your superiority! When you finally figure out that phasor angles (such as those used above) have no connection with the vector directions considered in the Poynting analysis then you will have found even more wisdom.

Zero *NET* energy moves in a standing wave pattern whether it be at a node or anywhere else. Forward energy and reflected energy moves across a node and everywhere else because there are no reflections in a homogeneous medium.

Please site a reference that says that reflections are possible in a homogeneous medium. Until you do that, you are preaching religion, not science.

I've always known that a graph drawn with a pencil on a piece of paper
is not an EM standing wave but, for awhile, you seem to have forgotten
that simple fact. The envelope is also not the wave.

EM waves necessarily travel at the speed of light in a medium. Does a
standing wave travel at the speed of light? If your answer is 'yes',
where does it go? If your answer is 'no', it is not an EM wave.

I challenged you to post the math, Gene, and you are apparently afraid
to do so. I'll bet you $100 that I am right and can prove it. I showed
that two plane waves in free space form standing waves with the total
E-field either 0 or 180 degrees apart from the H-field, contrary to
what you asserted. Please prove me wrong. If you cannot, please send
me $100.

If you would put aside your delusions of grandeur and simply sketch
those fields on a piece of paper, you would see for yourself that I am
right. When I get back home, I'll knock out a 3D graphic that will
leave no doubt.

Cecil,

This is truly bizarre. The E-field and the H-field are always at right angles to each other in the plane wave case. They are also perpendicular to the propagation direction. The same is true for the TEM mode in a coaxial waveguide, which is the usual case discussed on RRAA. There is no 0 or 180 degree involvement. I don't know what you are so confused about, but you really need to rethink what you are saying.

There is no need to sketch or calculate anything. A diagram showing the relationship of the E-field vector and the H-field vector is in every E&M and optics book I have ever seen. I presume that Hecht has the same diagram.

EM waves vibrate "up and down" at a frequency (say 4 MHz). The wavelength (say 80m) multipled by the frequency is the speed of light. But it goes nowhere.

The *stored energy* in the standing wave eventually encounters what we call "radiation resistance" which is nothing more than the tendency of nature to counteract current flow in the antenna. Nature opposes this current flow (this opposition gives rise to radiation "resistance") by creating TEM waves by maxwell's laws, which are released as the energy of radiation. Those travel at the speed of light. If the antenna had no contact with free space, and there were no ohmic losses, the standing wave would exist forever simply as stored/potential/reactive energy performing no work. The antenna in free space causes the stored energy in the standing wave to convert to TEM's that perform work due to nature attempting to create equal and opposing currents to the standing wave current by creating TEM radiating fields that form the opposing currents. (Lentz's law)

The little program I wrote shows that, on the line being analyzed, the energy is changing -- moving -- on both sides of a point of zero power. Energy is flowing into that point from both directions at equal rates, then flowing out at equal rates. This causes the energy at that point to increase and decrease. What zero power at a given point means is that there is no *net* energy moving in either direction past that point.

I'm ok with that. To me, it's the same as splitting the capacitor into
two separate ones, each with its own charge from one direction.

That's right. Although it's a true statement, I haven't seen any
explanation of why it would cause waves to bounce off each other.

How about this: During the initial turn-on of the system, energy does
cross the magic node. It's only in the theoretical limiting case of
steady state that the energy goes into and out of the node but doesn't
cross it. I'll argue that the limiting case can never be reached --
since this whole setup is a perfect construct to begin with. Or, if
that's not adequate by itself, what's the problem with energy being
trapped between nodes once the line is charged and steady state is reached?

I won't go there either.

This is done and graphically shown with the TLVis1 program demo. The
energy at each point is also calculated and shown.

> and after the pulses collide.

I think the basic problem here is assigning energy to each traveling
wave. It's taking you into exactly the same morass that Cecil constantly
finds himself in. He also concluded some time back that two waves which

collide had to reverse direction in order to conserve power, energy,
momentum, or something. Energy in the system is conserved; but nowhere
is it written that each wave has to have individually conserved energy.

> So...
>

Sorry, I'm having trouble following that. Voltage, current, charge, and
energy all in two sentences has too high a concept density for me to handle.

No, it'll have to be done without superposing power. Simple calculations
clearly show where the power is and where the energy is going, without
the need to superpose power or assign power or energy to individual waves.

>> I agree with your argument about two sources energized in turn, and have

> and the common explanations do not seem to hold up well.

I think you're partially right about that. Partially, because I think
there's an underlying assumption that the power in an individual wave
has to be conserved. If you do insist on assigning energy to individual
traveling waves, I think you have to be willing to deal with the fact
that the energy can be swapped and shared among different waves, and
stored and returned as well.

Our common analytical techniques deal with E and H fields which we can
superpose. In a transmission line, these are closely associated with
voltages and currents. They add nicely to make a total with properties
we can measure and characterize, and the total can neatly be created as
the sum of individual traveling waves from turn on until steady state.
It all works very well. Two fields, voltages or currents can easily add
to zero simply by being oriented in opposite directions -- and they do,
all along a transmission line. But how are the energies they supposedly
contain going to add to zero? You'll have to construct a whole new model

if you're going to require conservation of energy of individual
traveling waves. I'm absolutely certain that after all the work of
developing a self-consistent model with all interactions quantitatively
and mathematically explained and accounted for, we'll find a testable
case where some measurable result will be different from the
conventional viewpoint. (Google "ultraviolet catastrophe".) That would
then establish the validity of the new model. But I'm just as certain
that no such mathematical model will ever be forthcoming.

>> The advantage to the non-interacting traveling wave model

> > where the voltage or current is always 0.
>
> I can understand no energy crossing a zero current point, but how do you justify no
energy crossing a zero voltage point when current IS observed?

Well I start with P = V * I, so whenever the current or the voltage
is zero, there is no power. Specifically, V and I are measured at
the terminals of a network and P will be the power flowing into or
out of the network.

In the case under discussion, there are two networks, one to
the left of the point on the line and one to the right and
we are measuring the power flowing between these two networks.

For an example of current without power, consider a loop of
superconductor with a current flowing in it. No voltage, no
power, but there is current.

> Current is defined as movement of charges, and charges have energy by definition (how can
they be charges without energy?).

Consider an object flying through space. No work is being done
(and therefore there is no power), but the object still has
kinetic energy.

> Another point, the current is observed to change directions during the cycles, polarity
also changes on each side of the zero voltage point. Where might the polarized energy come
from if it does not cross the zero voltage point?

A thought experiment I have found useful is to consider a simple
resonant circuit made of an ideal capacitor and inductor. Charge
the capacitor to 10 volts and then connect the inductor. A sinusoidal
voltage and current will appear in the circuit.

Just as the inductor is connected:
- all the energy is stored in the capacitor
- the voltage on the capacitor is maximum
- there is no current in the inductor
After connecting the inductor:
- energy starts to transfer to the inductor
- the voltage on the capacitor is dropping
- the current in the inductor is increasing
Some time later:
- the voltage on the capacitor is 0
- the current in the inductor is maximum
- there is no energy stored in the capacitor
- all the energy is stored in the inductor
- no energy is moving from the capacitor to
the inductor
But the inductor insists that current continue
to flow:
- the capacitor begins to charge with a negarive
voltage
- energy begins to transfer from the inductor
back to the capacitor (note the change in the
direction of energy flow)
- the voltage on the capacitor is increasing
negatively
- the current in the inductor is dropping
Sometime later:
- the current in the inductor has dropped to
zero
- the capacitor has a maximum negative voltage
- all the energy is in the capacitor
And this continues forever at the resonant
frequency of the capacitor and inductor circuit.

But no energy is moving from the capacitor to
the inductor when the voltage on the capacitor
is zero and the current in the inductor is
maximum. It is at these times that the direction
of energy flow is changing, as well as when the
voltage in the capacitor is maximum and the
current is zero.

> I can kinda see how like charges could repell so that waves of like polarity might
"bounce" but I can't see how waves of opposite polarity might "bounce". If waves of
opposite polarity "bounced", why would the polarity change during the cycle on each side of
the "bounce" point?

An excellent counter-example. I may have fallen into
the trap of looking at the examples that support the
argument rather than looking for the ones that don't.
This will take some cogitating. Maybe its the end
of the line for the "bounce hypothesis".

> To me, it is much more rewarding to work with traveling waves that pass through one another, interacting to create standing waves.

I don't object to this view, as long as the waves are
viewed as having voltages or currents but no power.

The difficulty is that some waves definitely transport
energy while others do not and I do not see a good
explanation for what turns the former into the latter,
as happens, for example, when the pulses collide.

> Would it help your visualization process to observe that when two waves of SAME POLARITY but traveling in opposite directions cross, the currents accompaning the waves are moving in opposite directions both before and after crossing? When two waves of OPPOSITE POLARITY but traveling in opposite directions cross, the currents are moving in the same direction both before and after crossing.

I do understand (at least I think I do) the methodology
for superposing the waves of voltage and current,
computing the results and deriving the power from the
result.

I just am not happy that this results in waves sometimes
transporting energy and sometimes not, without a good
explanation of the transition.

> If we were talking about water, water behind a dam is like voltage, with the height of the water the potential energy, measured in head (feet), or PSI if measured at the bottom of the dam. A pipe to the bottom of the dam will squirt water at a high velocity but no head or PSI. The potential energy of the water behind the dam has been converted to kinetic energy measued in velocity of a moving mass. The moving water can be stopped, and if carefully done, the static head reached by stopping the water will nearly reach the original water level behind the dam. It would reach the same level if it were not for friction losses. Electrical current is something like that moving water.

Agreed. I have used this analogy as an aid to understaning
though it becomes challenging at RF.

872. Why the US airwaves are not free

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-15 14:55:16 UTC
From: Maverick Party <maverick_platform@yahoo.com>
Message-ID: <20c2844b-68da-48b2-8a2f-636920ca9e2a@f3g2000hsg.googlegroups.com>
Source record: 29488

The ruling democrat and republican parties proclaim that the airwaves "belong to the people." But if the people ever try to get access to any mass media that uses the airwaves, they would find these same parties tightly control them. The statement that the airwaves belong to the people is a hollow phrase that makes people feel good, as long as they never test it.

The American airwaves are almost completely dominated by large and wealthy private groups that broadcast their own opinions, not necessarily those of the people.

The democrat and republican parties want to control the airwaves for the same reason that totalitarian governments shut down any opposition media organizations. They want to censor the information that the mass of the people are allowed to know, in case the population gets too much negative information and wishes to throw the ruling parties out.

Secondly, when a political party is in power, it gets to dole out government contracts and licenses to private groups that petition it. What you don't see is that the halls of Congress and the regulatory agencies and the White House are crowded with lobbyists whose job is to distribute bribes to government officials for these privileges. In America, these bribes are promises of high-paying, do-nothing jobs like seats on Boards of Directors of corporations, and other nice jobs. Former senator Bill Bradley now sits on the board of Starbucks. These bribes are also called campaign contributions.

Now you know why the ruling parties, the democrat and republican, fought so hard to end freedom on the internet. Freedom of speech requires privacy and privacy requires anonymity. So to end freedom on the internet, these parties had to destroy any anonymity of speech you have on the internet.

Tyrannical parties, the Chinese communists and the American democrats and republicans, must be able to know who is spreading threatening political speech in any form of mass media because this threatens their control over the gravy train of government taxes and contract awards.

Since only 39% of the electorate vote in an American election, and the two parties are roughly even, this means that either party represents less than 20% of the eligible voters. But it costs nothing, only a signature to say you belong to one party or another, so the real percentage that either ruling political party in America represents is much smaller than 20%. So neither the democrats nor republicans, even

combined, represent a majority of even the electorate which is not even the the population itself.

The American ruling parties had a special problem. They had to shut down freedom of internet speech without appearing to be against free speech. They needed an excuse. They found the excuse in two ways. Terrorism and Pedophilia.

In order to take freedom and rights away from the people, a political party in power must first convince the people to give up their freedoms willingly. The democrate and republican parties used an old political trick. They had to convince the people there was a monster among them, and that they had to give up their privacy to the the ruling parties so the parties could protect them. What was this monster?

It was pedophilia. They could not do through the terrorism argument because the terrorist are really just a foreign group. The ruling parties chose pedophilia as an excuse to control the internet because pedophiles are normal people from the general population. They cannot be differentiated from the population, so they are invisible. An invisible is so much more frightening. The ruling parties made sure that their friends in the mass media like yahoo and the news agencies only broadcast stories depicting pedophiles as evil, and never allowing news stories in which pedophilia is depicted as good or neutral.

The ruling parties and other ambitious political groups, like lesbian-feminists and the christian right, were also competing with each other. Any group that could say that the invisible army of drooling pedophiles was more dangerous, and that it could protect the people even better, would gain political advantage.

Now you know how the ruling parties in the US took away the latest form of mass media that gave you freedom of speech. You also know why they did it.

If you ever make political speech that might be a threat to the ruling parties, these parties will know right where to find you and they will pick you off one by one. No will know that you are being picked off because they ruling parties will neve admit that that their reason was political speech.

Instead they will send a low-level agent around to your house when you are asleep or not at home. She will pick through your garbage and peek in your window. They will keep looking for some slight infraction or law they can charge you with. Even if the charge is thrown out of court, just fighting the case will bankrupt you and waste months of your life.

> node or anywhere else. Forward energy and reflected energy moves
> across a node and everywhere else because there are no reflections in
> a homogeneous medium.

From your posts I have not been able to determine exactly what
YOU mean by "*NET* energy moving". Several possibilities come to mind:
1) the time average of the instantenous power, P(x,t), at a
particular
point on the line.
2) the difference between the time average power in the forward and
reflected waves. This would be equivalent to subtracting the
forward and reflected power indicated by a Bird wattmeter.
3) the difference between the instantaneous forward and reflected
power at a particular time and point on the line.
4) the time average of the difference between the instaneous forward
and reflected power at a point on the line.
5) something completely different?

It would be valuable if you could indicate which of the possible
definitions of "*NET* energy moving" you mean.

It would be even more illuminating if you could describe what
measurements would need to be made on a line and exactly what
calculations should be performed to compute your definition
of "*NET* energy moving".

A rigorous definition might reveal that there is actually
agreement.

874. Circuitry of a radiator

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-15 16:10:06 UTC
From: art <aunwin@insightbb.com>
Message-ID: <c899fbef-6574-4d0d-88cc-c318bbdb81ca@e23g2000prf.googlegroups.com>
Source record: 29490

We all know that when a generator produces alternating electricity,
it produces it with a rotational movement only. At no time does the
generater
move backwards and forwards. When describing the value of the current
we can see that the current has a constant value as the rotor of the
generator
revolves. The current appears to be going up and down in value only
because
of the vantage point taken. If we view the generator from the side we
can see that
the vector angle of the current value is a segment of a revolution .
Thus it can be seen that what appears to be a change in magnitude of
the current,
is the effect, of a segment of the generators revolution.
The line that this generator connects to is a diamagnetic material
where the
energy in the line is a direct reflection of the position of rotation
of the generator's rotor.
This diamagnetic material is recognised by a skin on its surface as in
a patenna. which
is the dielectric(pattina in antique circles) between the center of
the material
and the outside surface and thus
represents a continuous capacitive connection which leads back to the
source .
There is a closed DC circuit at any moment in time. The outside of a
diamagnetic
material is where the current is actually active and where the
amplitude changes
according to the action of the capacitance up to that point. By
rotating the amplitude
changes it represents the rotative action of the current at that point
which by its
measure of rotation represents the fraction applicable to a revolution
other wise
known as a period with reference to the frequency of rotation.
We can now see the circuit as a reflection of the current amplitude
and its phase
with respect to the segment of a period that is depicted at that point
only which
is not physically connected to the vectors portrayed at any other
point in the
circuit. Thus when considering a single revolution only of a
generator we are

seeing at all times a continual DC current generation where the
apparent
amplitude of the current only reflects a constant current and the
portion of the
reolution or period that can be considered at that point. Thus when it
appears to have
maximum amplitude it is only a representation of the completion of
half a revolution
determined by the direction of the apparent current vector.
This electrical circuit is generally known as a 'tank circuit' which
does NOT have any
TRAVELLING waves OR any waves that BOUNCE since there is no
discontinuity
in the circuit at any point in time.
One can clearly see the true action of the current by using a crt that
reflects
the phase changes applied to the constant current values generally
known as
a spectrum analyser where what is seen as the angular position of a
true dipole
that is part of the molecular structure of the material as a whole.
and where
resonance is depicted by the angle of the internal dipole at the
circuits source.

If I have made errors in spelling I apologise.
Best regards

Can anyone point me to any information about the Filipino Monkey maritime radio heckler? The guy made the news this week, and their's a lot of talk about him, and it's been claimed that he's been at it since the 80's, but everything that comes up on the web or usenet seems to be less than a week old. Could this guy really be as well known as is claimed without any documentation, or is there old information that I can't find because it's being drowned out by the new?

Why would that be so hard to do anyhow? Employees who are not civil to
other employees "go someplace else" eventually.

Not a matter of enforcement, just a matter of slowly adjusting the
workplace. A few well placed letters in the offending employee's HR
file, and yer covered.

Hate to rain on the parade, but a fully function generator can be built
using exclusivley forward and backward motion. No rotation needed.

The simplest commercial application of this is the "Faraday Flashlight,
which charges a supercapacitor by strictly linear back and forth
movement of it's generator.

Even a loudspeaker is a linear generator.

880. Universal laws of the sciences

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-15 18:09:46 UTC
From: art <aunwin@insightbb.com>
Message-ID: <ddea9cfe-5603-4a90-888e-a45a62177e15@z17g2000hsg.googlegroups.com>
Source record: 29496

All the laws of the universe are directly a reflection of the action that Newtons laws
pertain to. All Newtons laws pertain to relative movement of mass which is comprised of time, mass and relative distance to form a state of equilibrium.
We all know how mechanical laws are conneted to Newton but how is electricity essentially the same? We all know that magnetism is a reflection of the smallest dipole
relative angle at any point in time. We also know that this dipole can also turn during a period of time such that the magnetic field of force at any point in time is reflected by the angle that the dipole takes. This dipole in electrical terms is a microsom of the large mechanical forces in relative movement.
For electricity the dipole takes up an alignment that reflect the current flow at any point and place in time. Thus with a dc current all the dipoles aligne with each other with respect to the current flow in a two dimensional form. When applying an alternating current we are also really applying a DC current but with a rotational or three degrees of freedom such that at any point in time all dipole alignment reflect the torque angle at that particular point which is NOT the same as any other dipole point alignment.
Thus when current is not applied the molecular dipole arrangement fall back to the directions it had prior to the onset of current to provide a stated of equilibrium.
In the case of a DC current supplied the microscopic dipoles ALL have the same alignement and when the current ceases to be applied the dipoles still stay in alignment with each other. So in effect ,the movement of the micro dipole in electricity is exactly the same as a mechanical element where all the forces of the electrical dipoles are summated. There are difference with mechanical elements which can be determined by its mass and structural make up such as how they perform in a magnetic field. Earlier we expressed the strength of a magnetic field is measured in part by the angular position of its resident dipoles.For a true magnet formed with a ferrous material the atmosphere can permeate all of the material as it changing its composition, but in the initial state the total mass is a reflection of the number of inherrent dipoles which in summation is a measure of the potential energy contained. With a current carrying
element such as aluminum when it is exposed to the atmoshere it immediately forms a barrier to prevent the ongoing penetration of oxidtion. Thus when a current is applied
it can only affect the dipoles in the protective skin depth of the pattina and not affect the internal unoxidizes material where it can oxidize and decay as with a ferrous material.

Thus the pattina can only hold a smaller number of dipoles which
reflects a smaller potential energy for generating a magnetic field.
Thus both electrical and mechanical
formats surround the facts of potential energy and kinetic energy when
in a state of equilibrium as espoused by Newtons laws.
Have a happy day
Best regards

In this modern world, too many people mistake good manners for weakness.
I've had to demonstrate the fallacy of that on occasion.

A person without good manners isn't equipped with all the tools needed
to be highly successful. Those without manners can become successful,
but it is in spite of those poor manners, not because of it.

The bottom line is that the angular position of the inherrent dipole
at any point
reflects the amount of kinetic energy available in a magnetic fiels at
that particular point.
Whereas, at all points the angular position of the multitude of
vectors is not the same.
This being contrary to DC flow where the inherrent dipoles are aligned
in unison with two instead of three degrees of freedom as with an
alternating current. It is this subtle difference which is causing
such confusion on this newsgroup which can only be visuallised by the
newsgroup when all are assumed to have only two degrees of freedom.
Good thing is that even with what you are referring to you have
identified the three degrees of movement which others cannot get a
handle on with respect to alternating current.

Look, let me be honest here, when I walk into a place and want/need/request something--I simply want it; if I find a nice person able to fulfill that want/request--it is icing on the cake. But, just give me my request!

What I keep running into in life are places where the employees are all arranging the situation to "please" themselves (that usually means they "get rid" of qualified individuals who are a "threat" to their job position) with a great work environment and service sucks (indeed, I am now ending up with "pleasant" a-holes in India/china/Malaysia on help lines! This REALLY peeves me!)--it is a job, yanno? That is why they call it "work!"

Now if both can be accomplished, great service AND a wonderful and nurturing environment for "them"--GREAT! I can't be fooled--I KNOW THE DIFFERENCE! :-D

Regards,
JS

I can see why you find "no power" at the zero voltage point, but does that imply that there is no energy flow and no power from every perspective? As I write, I am struggling how to clearly differentiate between "power" as "work done" and energy as "capacity to do work", and what "network" are we defining.

Let's begin with the network. Drawing from your words below, we have two networks, one to the left and one to the right of our zero voltage point. When we test voltages on either side of the zero point, we find voltage. The question now is: "Which network did we join when we measured voltage?". The answer is: "We joined the network that we measured.". When we measure exactly in the center between networks, we join neither network.

For another way of looking at the two networks, let us place our voltage probes on each side of the zero voltage point on a/the wire connecting the two networks. We will detect a voltage and a current for any of the standing wave systems we are discussing. By changing our points of reference, we find that power is applied to the zero voltage zone during the instant of time the measurement is made.

I personally define power as a state/condition where "work 'is being' done", . Power must act over time and have a physical movement component. Voltage by itself does not fulfill this definition because no movement is observed. Current is movement, voltage is only an indication of where a concentration of charges is found.

> power, but there is current.

I agree. We could place voltage probes between any two points on the superconducting loop and not find voltage. Power is not being applied nor extracted from the superconducting loop system. I think we would all agree that energy is stored in the superconducting loop with current flowing.

When the voltage on the capacitor is zero, the voltage on the entire system is zero, no matter our reference point. The system energy is completely contained in the moving current with a direction of energy flow completely defined. For an instant, the inductor is like a superconducting loop.

From a traveling wave standpoint, the resonant capacitor/inductor system contains a positive wave and a negative wave, equally balanced energy wise. When the capacitor is completely charged, the positive and negative waves are at the reversal/mid point of the cycle where each wave is maximally displaced from center (which is at the electrical center of the inductor). When the capacitor is completely discharged, the two waves superimpose and both reside in the inductor at identical times. The energy of both waves is completely contained in the electromagnetic field that exists outside the wires containing the two traveling waves. Do the waves exist on the wire at this instant, or have they completely desolved into a space field we observe as magnetic force? The current seems to be flowing so I would say the waves both continue to exist.

>

Have you considered how energy is transfered between elements of the transmission line over time if we do not have an ongoing application of power? Doesn't one section of line apply power to the next successive section of line an instant of time later after it received applied power? We agree that a transmitter applies power at the input of a transmission line. Isn't the first section of transmission line just the power source for the second piece of line?

I think of the traveling waves as transporting power and energy through time and physical distance. The highest voltage points physically "move" (found in a new location) as time passes, as do the highest current points, and always together in phase.

>
> The difficulty is that some waves definitely transport
> energy while others do not and I do not see a good
> explanation for what turns the former into the latter,
> as happens, for example, when the pulses collide.

Some waves transport energy, and some do not! That distinction bothers me less now that I have participated in this thread for a while. For me, the traveling wave always has current and voltage in phase, and always carries power. If I can not find power, then we must have a standing wave. For me, traveling waves is all that we really have, they are primary. All other waves flow/result from the traveling waves.

Another observation that has helped me is the recognition that "waves" are just statistical groupings of repetitious events. It is very convenient to treat waves as physical objects but they are really groupings of much, much smaller events. How small is the smallest event, no one seems to know, but the highest frequencies still seem to be electromagnetic events. If the "wave" is composed of a group of much smaller events (such as movement of electrons, or smaller), then it is not so hard to accept that we might detect passage of two waves as having a different voltage and energy level from what we would expect if the voltage and energy were static.

>
> > Would it help your visualization process to observe that when two waves of SAME POLARITY but traveling in opposite directions cross, the currents accompaning the waves are moving in opposite directions both before and after crossing? When two waves of OPPOSITE POLARITY but traveling in opposite directions cross, the currents are moving in the same direction both before and after crossing.

A plot is simply the graphical representation of an equation. Since I
was the one pointing it out to you, it seems you are the one who had
"forgotten that simple fact".

The envelope is also not the wave.

It all comes from the same equation, Cecil. If the thing which
amplitude modulates a wave cannot be called a wave, then what should
it be called?

Source record: 29353

A radiator is made from a myriad of capacitors and inductors
in the formof a myriad of loop circuits along the length of a
radiator.
When energy is transferred from the generator the angular direction
of the inherrent dipoles must be at the same angle with respect to
time.
Same goes for the angular position at return. This places all in a
frame
of equilibrium. It the angle is not the same there is obviously a
mismatch
which the generator cannot correct with a instantaneous change of
phase.
If the phases are different at the beginning it can be seen as out of
equilibrium
at the end also which can worsen for every pont along the radiator
circuit.
The difference in angular direction of the micro dipoles is a measure
of
the change in real current amplitude compared to the angle taken
later
at that point and that point only.
Though a radiator has a multitude of like components, with its
similarities
we can look at an individual cuircit as a representitive of the whole
which
multiplied at a later time to reflect the time of one period or
revolution.
The loop circuit is made up of a parallel circuit consisting of an
inductance
and a capacitor. Ofcourse the circuit itself consists of resistances
which
allows current to flow thru its center to generate heat. But at this
time
we can all accept the presence of resistance. Both of the components
alluded to recieves energy initially in sino soidal form and then
stores
that energy. But with both components being mirror image with each
other
they take turns in their operation of storing energy.each dependent on
the
phase of the inherrent micro dipoles. They also have the ability to
empty
out the stored energy which is in a form totally unlike the sino
soidal form

of collection. In fact the discharge is synonymous with an explosion with each
storage vessel collecting the contents of the others explosion. We must
recognise that these exchanges also lose energy which fortunately the
generator replaces continuesly to replace the energy lost ,say to resistance
heat e.t.c The change over point of collecting energy of both storage
components.is the relative phases of their individual energy content voltage
which in a tank circuit are constantly changing with respect to the phase angle
of the current such that when the phases of voltage and current is the same
it then becomes a DC current and removes itself from its container.
Thus the mechanism between the inductance and capacitance is the depository
of energy between themselves where the time varying energy, which reflects
the time constant of the energy reservior, generates an external magnetic field.
At the same time an external sino soidal current is in constant supply from the
generator to replace energy lost in the above stated interchanges and resistances.
Tomorrow we will examine how these above internal actions lead to the radiation
phenomina that allows information to be passed from a radiator to another like radiator
or receiver via propergation of potential energy.
Have a happy day

Roger you would be better to start off with first principles. Current
is by definition
a constant at all points where the imagianary vector is the angle or
phase of
a molecular dipole at the point of reference. Nothing is moving
forward. The only movement
of the molecular dipole is on of rotational movement about a static
pont of reference.
One you understand this you can then go on to magnetic fields created
by multiple
inherrant dipoles with respect to their phase angle which magnifies or
nullifies
the created magnetic field
Best regards

As I write, I am struggling how to clearly differentiate between "power" as "work done" and energy as "capacity to do work", and what "network" are we defining.

Power at a particular point on the line is the rate of energy flow past that point. It does no imply that any work is done anywhere, since any energy flowing past the point can be stored. That is, in fact, exactly what happens with the open circuited line in my analyses and illustrated with TLVis1. You can see from the TLVis1 demo 4 that power is present at all times and places along the line except a few select points. No work is being done; energy is simply moving back and forth along the line and between the E and H fields.

Of course you're free to define anything in any way you choose. But you've chosen a definition that's different from the one accepted in all of electrical circuit analysis and all textbooks. So you can expect to have a good deal of difficulty communicating with people who are acquainted with the universally understood definition and assume that's what you mean, rather than your own personal definition. To them, power is the time rate of energy flow, dE/dt, period.

What you are saying is 100% correct for plane EM traveling waves.
What you are saying is 100% incorrect for standing waves. It just
shows that Hecht was right when he said standing waves probably
don't deserve to be called waves. Maybe you should try to understand
why Hecht would say such a thing.

Yes, and that diagram is for a *TRAVELING WAVE*, not for a standing
wave. Please find a reference with the E-fields and H-fields diagrammed
for a standing wave and get back to us. Better yet, consider there is
a need to sketch the fields if for no other reason, just to prove me
wrong.

This is not rocket science, Gene. When the magnitude of the Poynting
vector for the forward wave equals the magnitude of the Poynting vector
for the reflected wave, the net Poynting vector is obviously zero.
Since the Poynting vector equals ExH, the only way that the standing
wave Poynting vector can be zero everywhere is for the cross product
of ExH to be zero. The cross product is E*H*sin(A) and we know that
E and H are not zero, so sin(A) must necessarily be zero. So A must
necessarily be 0 or 180 degrees. Nothing else is possible.

Exactly! But that does not preclude the forward Poynting vector
being equal in magnitude to the reflected Poynting vector.

John ,
Companies want to cut down labor costs on the assumption they sell to
employees of other companies who apparently have the money to spend.
This disregards his own employees buying power..
Unfortunatly the workers at other companies also have had their wages
cut such that the premise
that employees can afford the products of employers is false. Thus the
manufacture of products or inventory must be adjusted to concurr with
existing buying power. But the benefits of reduced labor costs were
pocketed by the employer while the purchasing price of the product
stayed the same or went up. Because the employee is now earning less
he needs assistance to get by. The costs of this is passed on to the

supplier in the form of taxes who imediately passes the addition to
the consumer. And so it goes on until the round about comes to a halt
and its riders raid the hoard that the employer pocketed by force.

I wish you would stop using you guru status to misquote people.
During wave cancellation, the waves do *NOT* "collide". They
cannot collide since they are traveling in the same direction.
I just read on a plane trip today where Ramo & Whinnery talk
about wave cancellation. When waves are canceled, their energy
components have to go somewhere.

I disagree with Roy's last sentence. If an EM wave exists, it's
Poynting vector is ExM. The energy in that individual wave *must*
be conserved. If that energy is not conserved, the conservation
of energy principle is violated.

Net energy is the difference between the average forward
energy and the average reflected energy. Please forget
instantaneous values. Instantaneous voltage and current
are obviously valuable concepts. For the context of this
discussion, seems to me instantaneous energy or power are
just diversions away from the real issues.

The real question is: Can an EM wave exist without energy?
Roy implies that it can. I challenge him to produce an
EM wave containing no energy.

I could be wrong, but don't E-fields and H-fields from traveling waves
superpose to form net E-fields and H-fields? Wouldn't the net fields
have vectors whose direction and magnitude are determined by the
vectors which correspond to the traveling wave fields? Wouldn't the
net field generated by a radiator having these waves traveling on it
look like a standing wave? Is there any reason to consider standing
waves on an antenna other than as a simple way to analyze its
radiation pattern?

When a wave is canceled, there is no wave. Therefore there can be no energy associated with that wave. If there is energy, then it must be associated with a wave that is not canceled. Same thing is true when I have candy. If it's not in my left hand, then it must be in my right hand. It's all very profound.

I'll buy that, Jim. I believe that Hecht left out the adjective,
"EM". If he meant standing waves don't deserve to be called EM waves,
I agree 100%. However, standing waves seem to meet the broad definition
of "wave".

Of course. Now try to convince Gene of that fact of physics. In
spite of his earlier assertions about the differences between
traveling waves and standing waves that agreed with my side of
the argument, he seems to have switched sides. (For political
reasons)?

Cecil,

I have no idea why you would introduce "political reasons" into this, but no matter. My head hurts from pounding it into the brick wall, so I will give up.

It would be really amusing to see you scramble to rotate the vector axis of the magnetic field (or the E-field) as it reflects from an interface. Since the E-field and H-field are related by curl relationships as shown in the Maxwell equations, it would be interesting to see how one could have related E-fields and H-fields at "0 degrees" and "180 degrees" as you claim. As a self-proclaimed math expert I am sure you understand the properties of the curl operator.

This is very basic stuff, and it is in the standard textbooks, probably even in Hecht.

Actually, here is what *really* happens: Given; You have a generator. Npw consider the circular motion of the rotor of the generator. Let us choose to put 2 permanent magnets on the rotor and electromagnets on the 2 stators which are comprised of wires wound around 2 ferromagnetic cores. We begin at equilibrium with the N pole of the rotor midway between the N and S poles of the stators.Now turn the rotor in the direction of opposing magnetic fields; as the N pole of the rotor approaches the N pole of the stator, a current is produced on the terminals of the stators. At the midway position where we started, the current was minimum (0). As the two N poles become closest together, we have a maximum current (positive). Then we approach midpoint between N and S on the second stator and we have zero again (at 1/2 wave or 1/2 rotation). Then we have the closest proximity of N and S which gives us a minimum current (negative). The back to midway between N and S on stator 1 and we are back at zero and have completed one rotation/cycle/one wavelength. The constant angular velocity you speak of, omega, defines the constant frequency of the rotation (2*pi*f). The angle of the rotor. at any point in time is 2*pi*f*t. At any position, the current can be defined at Imax*sin(omega*t). That is where your theory breaks down, art. True, the rotation is a constant velocity but false, the current is not constant as the generator revolves; it depends on the relative position of the rotor and stators.

Art knows how we visualize this positioning. He knows that if we were to take a clear disk (that we can see through) and paint a red dot on the outside of the disk, then rotate the disk at a constant velocity, then turn the disk 90 degrees so you are watching the edge (taking a 90 degree vantage point), you see the red dot moving up and down at an irregular rate; from this position it is NOT a constant velocity anymore, The up and down movement represents the "y" axis of a sine wave. Now, if you can attached a pen recorder to the dot and have it contact a moving strip of paper turned another 90 degrees to the revolving circular disk, AND move the paper at a constant linear velocity, we have the "x" axis of the sine wave representative of time or "t". With proper calibration and normalization,

this sine wave traced by the pen recorder will be a depiction of the current wave form in the generator.

The wave form is a sinusoid even though the generator moves in a constant circular motion. But you can see that the current is by no means constant at all.

How does the fact that the current is demonstably a sinusoid (as well known fact, not theory), and not a straight line, affect your theory?

I would imagine it puts you back to the drawing board, way at the beginning, again, as has happened so many times before.

It reminds me of the king counting has pennies, "....on million one, one million two, one million three...crash! (the coins fall to the floor from their weight). One, two, three...". (The king WAS persistent ;-))

It certainly applies to EM waves but what you are missing is
that it doesn't apply to standing waves which are NOT EM waves.
Tomorrow I will list the Ramo & Whinnery characteristics of
an EM wave. Standing waves don't meet those characteristics.

Now for the real question. When the net instantaneous
power is 0 at a point with non zero power on each side
of that point, is any energy transferred?

The answer is - of course - equal amounts in either
direction. The sum of the two Poynting vectors is
zero.

Until you can provide a reference or example of a
reflection occurring in a homogeneous medium, you
have proven nothing except that you can fantasize.
Ramo & Whinnery imply that reflections are impossible
unless the reflection coefficient changes magnitude
which it doesn't with a constant Z0.

> When a wave is canceled, there is no wave.

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

The canceled waves are "not annihilated" even though there is, as
you say, no wave in the direction of cancellation. The energy in
the canceled waves is "redistributed" in the opposite direction
in the transmission line as constructive interference. We hams call
that event a "reflection".

Are you objecting to my link between power and work?

I can understand how we might think of a moving voltage wave (on a transmision line) somewhat like a battery that moves along a straight line. With that view, there would be no power acting on the line, no work, and there would be no evidence of current.

If a capacitor discharges, work is done on the circuit receiving the discharge. It takes work to charge a capacitor. Are you thinking that on a continuous capacitor like a transmission line the energy just "slides" along (like a train on tracks) without change of energy, like a battery moving along?

In my view, logic demands a smooth flow of power and energy from source to load. We should be able to account for both energy and power for every instant of time, over every inch of distance. I thought you were doing that in TLVis1 demo 4.

>
> > . . .
>
> > I personally define power as a state/condition where "work 'is being' done", . Power must act over time and have a physical movement component. Voltage by itself does not fulfill this definition because no movement is observed. Current is movement, voltage is only an indication of where a concentration of charges is found.

Are you again objecting to my link between power and work?

This definition sounds consistant with power flowing on the transmission line. We seem to fulfill the power definition of energy flow on a transmission line but you make the statement "No work is being done". Would you object to my example of requiring work to charge a capacitor?

>
> Are you objecting to my link between power and work?

I have to correct my statement.

The strict definition of work is the same as energy. So moving energy is technically doing work, even if no energy is being dissipated or being put to any useful purpose. What I meant but failed to say accurately is that no net work is being done. All energy being moved is being moved back. None is being converted to heat (dissipated), mechanical energy, or other useful work.

Consider a resonant circuit or, for that matter, an open or short circuited transmission line. Energy is moved back and forth each cycle, resulting in non-zero power, but without any *net* work being done.

It's possible that by "power" you mean "average power", which is not the same as (instantaneous) power. (This is exactly the mistake I made, using "work" to mean "net work".) The average power (and net work done) is non-zero whenever the amount of energy moved in one direction during one half the cycle isn't equal to the amount moved the other way during the other half of the cycle.

> I can understand how we might think of a moving voltage wave (on a transmision line) somewhat like a battery that moves along a straight line. With that view, there would be no power acting on the line, no work, and there would be no evidence of current.

Sorry, that doesn't make sense to me. A traveling voltage wave on a transmission line is always accompanied by a current wave, and the ratio

of voltage to current is equal to the line's Z0 at every point and every
time.

> If a capacitor discharges, work is done on the circuit receiving the discharge.

That's true. No net work is necessarily done -- if it's discharged into
an inductor, the energy is simply stored in the inductor, and returned
later by the inductor doing an equal amount of work on the capacitor.

> It takes work to charge a capacitor.

Yes, in the strict instantaneous sense.

> Are you thinking that on a continuous capacitor like a transmission line the energy just "slides" along (like a train on tracks) without change of energy, like a battery moving along?

A transmission line has both distributed capacitance and inductance.
Energy moves between the two. The little program TLVis1 I created and
posted a link to shows this graphically in demo 4, with the energy
stored in the capacitance being in one color and the energy stored in
the inductance another color. You can clearly see how the energy moves
back and forth between the two each cycle.

> In my view, logic demands a smooth flow of power and energy from source to load.

Your logic is flawed. A load which contains both resistance and
reactance has energy flow in one direction during half the cycle and
energy flowing the other direction during the other half. Because of the
resistance, the two aren't equal; the difference is the energy being
dissipated each cycle. If the load is an open or short circuit, no
energy flows to the load at all. If the load is purely reactive, it
stores the energy for half the cycle and returns it during the other half.

> We should be able to account for both energy and power for every instant of time, over every inch of distance. I thought you were doing that in TLVis1 demo 4.

I am indeed. It shows exactly that. If you'll look carefully at the
graphs, you'll see that it demonstrates what I've said above.

>>> . . .
>>> I personally define power as a state/condition where "work 'is being' done", . Power must act over time and have a physical movement component. >
> Are you again objecting to my link between power and work?

I apologize for my careless use of "work". Instantaneous power is the rate of flow of energy, or work. Average power is the average rate of flow of energy or work. If the average power is non-zero, net work is being done, e.g., energy is being dissipated in a resistance or being radiated. But instantaneous power can be non-zero without this occurring.

> This definition sounds consistant with power flowing on the transmission line.

Which definition, yours or the one used by everyone else involved with electrical circuits? I maintain that power doesn't "flow". Energy flows, and power is the rate of that flow. The standard definition says nothing about power "flowing", on a transmission line or anywhere else.

> We seem to fulfill the power definition of energy flow on a transmission line but you make the statement "No work is being done".

Please correct that to be "no *net* work is being done. It was made to refer to the open-circuited line in my example. The average power everywhere is zero, as you can see from demo 4 - the power waveform oscillates equal amounts on both sides of zero. No net energy is being transferred or dissipated.

> Would you object to my example of requiring work to charge a capacitor?

I stand corrected - work is required. But the work can be returned.

So you seem to be claiming that the following two
statements can be simultaneously true:

1. Power [recall p(t)=v(t)*i(t)] is the rate at
which energy is transferred.
2. Energy can be transferred when the power is zero.

To my simple intellect, one of these statements
must be false.

"*net* energy moving" seems to be a bit of a dangerous notion.

If "*net* energy moving" is the time averaged power, then
it is zero at *every* point on the line under consideration.
And I do not mind this definition.

But at the points where the current or voltage is always
zero, it seems to me unnecessary to use the qualifier "*net*"
since the power IS always zero [from p(t)=v(t)*i(t)]. That
is, unless you are introducing another interpretation of
"*net*".

I agree. And when looking at sinusoidal excitation with "standing
waves", it easy not to assign energy.

But when looking at pulses, the energy in the pulse seems to jump
out at me, and it is hard to ignore.

> It's taking you into exactly the same morass that Cecil constantly
> finds himself in.

I know. And I definitely do not want to go there.

And yet, when I look at pulses, where the energy is clearly visible,
I develop some sympathy for Cecil's position.

Possibly, but the energy is so clearly visible in the pulses before
and
after they collide.

> energy all in two sentences has too high a concept density for me to handle.

I'll try with a better description. Consider a line 4 sec long with
a matched pulse generator at each end. There is an instantaneous power
(p(t)=v(t)*i(t)) meter at the 1, 2 and 3 sec points on the line.
Call them the left, middle and right meters.
The left generator launches a 1 sec pulse of 100 volts and 2 amps (it

is
50 ohm line). This pulse is 200 W and contains 200 J.
Simultaneously the right generator launches a 1 sec pulse of 50 volts
and 1 amp (50 W and 50 J).
At 1 sec the left power meter reads 200 W for 1 sec as 200 J pass,
then at 3 sec the right power meter reads 200 W for 1 sec as 200 J
pass. It sure looks like the pulse has travelled down the line.
At 1 sec the right power meter reads -50 W for 1 sec as 50 J pass,
then at 3 sec the left power meter reads -50 W for 1 sec as 50 J
pass. It sure looks like this pulse has travelled up the line.
The total energy transfer measured by the left meter is 150 J and
by the right meter is also 150 J.
At second 2, when the pulses collide in the middle, the middle meter
reads 150 W for 1 second. So the total energy transfer at the middle
is 150 J, which is good since it agrees with the totals in the other
meters.

So the middle meter reads 150 W.
The left meter reads 200 W and later -50 W.
And the right meter reads -50 W and later 200 W.

So how does a pulse that measurably is 200 W (measured at both right
and left meters) move through a point that only measures 150 W.

Numerologically it surely does appear that one can superpose powers
since 200+(-50) is 150.

The main difference between this experiment and one with steady state
sinusoidal waves is that in the latter the component forward and
reverse waves in are derived by arithmetic from the actual conditions
on the line and it is easy to wave the issues away by saying that the
component waves have no reality. They are just intermediate results
in some arithmetic.

This waving away is much harder to do for the pulse case because
the pulses can be individually observed as actual conditions on the
line.

> > So the challenge is not so starkly obvious as it is when the

> clearly show where the power is and where the energy is going, without
> the need to superpose power or assign power or energy to individual waves.

Yes. And I find it easy to obscure for the sinusoid case. But the
pulses
seem to make it easy to measure and not so easy to refrain from

assigning
energy and power to the pulses.

[snip]

But then, what is the mechanism that swaps the power between the
pulses
and changes the direction of the energy flow?

I agree. And it especially will fail if instead of dealing with
the sum of the reflected waves, we try to sum the power of each
reflection
individually.

And yet, the power and energy are so visible when looking at pulses.

> I'm absolutely certain that after all the work of

I do not expect that to happen. But how is the energy in the left
travelling
50 W pulse turned around at the middle to add to the 150 W that is let
through
to complete the 200 W right travelling pulse?

I agree with you. If energy is measured in joules and energy flow
is measured in joules/sec, then it seems to me that if power is
measured in watts, then "power flow" would have the dimensions of
watts/sec or joules/sec^2, which doesn't make any technical sense.

The units of the power-flow vector are watts/unit-area. That's
a value fixed in space-time and that value is not moving.

However, most of my college textbooks from the 50s refer to
"power flow" as do some folks on this newsgroup.

For instance, Ramo & Whinnery talk about an "electromagnetic
theorem concerning *flow of power*".

> A transmission line has both distributed capacitance and inductance.
> Energy moves between the two. The little program TLVis1 I created and
> posted a link to shows this graphically in demo 4, with the energy stored
> in the capacitance being in one color and the energy stored in the
> inductance another color. You can clearly see how the energy moves back
> and forth between the two each cycle.

Now it is my turn to wax technically correct. If the energy in
a standing wave is indeed flowing back and forth between an
inductance and a capacitance, then a standing wave is *NOT* an
EM wave just as the EM energy flowing in a tank circuit doesn't
meet the definition of a wave. Ramo & Whinnery list the properties
of a uniform plane wave: [begin quote]

1. Velocity of propagation, v = 1/SQRT(permeability*permittivity).
2. No electric or magnetic field in direction of propagation.
3. Electric field normal to magnetic field.
4. Value of electric field is the intrinsic impedance (ii) times
the magnetic field at each instant.
5. Direction of propagation given by direction of ExH.
6. Energy stored in electric field per unit volume at any instant
and any point is equal to energy stored in magnetic field per
unit volume at that instant and that point.
7. Instantaneous value of Poynting vector given by
E^2/ii = ii*H^2, where E and H are the instantaneous values of
total electric and magnetic field strengths. [end quote]

A standing wave doesn't satisfy any of those properties.

Since we are dealing with superposed waves that would
be the rate at which net energy is transferred.

> 2. Energy can be transferred when the power is zero.

> To my simple intellect, one of these statements
> must be false.

Using the rules for superposition, treat each wave
separately and superpose them for a net result.

And it certainly depends upon what definition of "transfer"
that you are using. I am using, from Webster's:

"transfer - move"

Would you please post your definition of "transfer".

The forward wave is moving energy across the zero power point.
The reflected wave is moving an equal magnitude of energy in
the other direction across the zero power point.
The Poynting vectors for the forward wave and reflected wave
are equal in magnitude and opposite in direction. There is
of course zero net power transfer and points where the
net instantaneous power equals zero.

I'm going to keep reminding you that, until you provide
a reference or example of reflections occurring within
a homogeneous medium, nothing that you have to say
about the subject is linked to reality.

A standing wave is the *net* result of the superposition of
the forward wave and the reflected wave (without which the
standing wave would not exist). Anything, including power,
calculated using standing waves is necessarily a *net* result.
Superposed voltage is a net voltage. Superposed current is
a net current.

As I write, I am struggling how to clearly differentiate between "power" as "work done" and energy as "capacity to do work", and what "network" are we defining.
>
> Let's begin with the network. Drawing from your words below, we have two networks, one to the left and one to the right of our zero voltage point. When we test voltages on either side of the zero point, we find voltage. The question now is: "Which network did we join when we measured voltage?". The answer is: "We joined the network that we measured.". When we measure exactly in the center between networks, we join neither network.

That is the best way. And that way we can measure the flow between the networks.

> For another way of looking at the two networks, let us place our voltage probes on each side of the zero voltage point on a/the wire connecting the two networks. We will detect a voltage and a current for any of the standing wave systems we are discussing. By changing our points of reference, we find that power is applied to the zero voltage zone during the instant of time the measurement is made.

But if we move the probes, we have changed the amount of 'network' on either
side.

> I personally define power as a state/condition where "work 'is being' done", . Power must act over time and have a physical movement component. Voltage by itself does not fulfill this definition because no movement is observed. Current is movement, voltage is only an indication of where a concentration of charges is found.

I am not convinced about 'physical'. Consider heat, light.

> When the voltage on the capacitor is zero, the voltage on the entire system is zero, no matter our reference point. The system energy is completely contained in the moving current with a direction of energy flow completely defined. For an instant, the inductor is like a superconducting loop.
>
> From a traveling wave standpoint, the resonant capacitor/inductor system contains a positive wave and a negative wave, equally balanced energy wise. When the capacitor is completely charged, the positive and negative waves are at the reversal/mid point of the cycle where each wave is maximally displaced from center (which is at the electrical center of the inductor). When the capacitor is completely discharged, the two waves superimpose and both reside in the inductor at identical times. The energy of both waves is completely contained in the electromagnetic field that exists outside the wires containing the two traveling waves. Do the waves exist on the wire at this instant, or have they completely desolved into a space field we observe as magnetic force? The current seems to be flowing so I would say the waves both continue to exist.

When using lumped elements, I do not think I would try to write a
description
in terms of waves.

> > > I can kinda see how like charges could repell so that waves of like polarity might "bounce" but I can't see how waves of opposite polarity might "bounce". If waves of opposite polarity "bounced", why would the polarity change during the cycle on each side of the "bounce" point?

> > viewed as having voltages or currents but no power.

>
> Have you considered how energy is transfered between elements of the transmission line over time if we do not have an ongoing application of power? Doesn't one section of line apply power to the next successive section of line an instant of time later after it received applied power? We agree that a transmitter applies power at the input of a transmission line. Isn't the first section of transmission line just the power source for the second piece of line?

Yes. And that is especially visible when the line is excited with a
pulse.

> I think of the traveling waves as transporting power and energy through time and physical distance. The highest voltage points physically "move" (found in a new location) as time passes, as do the highest current points, and always together in phase.
>
>
>
> > The difficulty is that some waves definitely transport
> > energy while others do not and I do not see a good
> > explanation for what turns the former into the latter,
> > as happens, for example, when the pulses collide.
>
> Some waves transport energy, and some do not! That distinction bothers me less now that I have participated in this thread for a while. For me, the traveling wave always has current and voltage in phase, and always carries power. If I can not find power, then we must have a standing wave. For me, traveling waves is all that we really have, they are primary. All other waves flow/result from the traveling waves.

But then do the two travelling waves that make up the standing wave
transport
energy? When no energy crosses the voltage or current zeroes?

And when there are multiple reflections, there are multiple travelling
waves
in each direction. Do each of these multiple travelling waves
independantly
transport energy?

And even a standing wave has energy moving. Just not past the voltage
and
current zeroes.

> is the mechanism that traps the energy?

Photonic energy cannot be trapped in a homogeneous medium.
It is simply impossible to accomplish that feat without
any discontinuities to cause reflections.

The energy components are not trapped. There is exactly the
amount of energy in the line as required to support the
forward wave and reflected wave. The concept of trapped
energy is an illusion, an artificial shuffling of the
component energy. Modulation will reveal exactly
what is happening. I like TV ghosting examples.

Standing light waves can happen in free space. There is no
mechanism that traps the energy because there is no trapped
energy.

>> is it written that each wave has to have individually conserved energy.

For the record, what Roy said above is a false statement.
Canceled waves are necessarily moving in the same direction
at the same speed. It is impossible for them to collide.

Roy cannot produce even a single example where I said
colliding waves reverse direction in a homogeneous medium.

And it is certainly written that *all* energy, individual or
not, must be conserved. Not only must the energy in each
wave be conserved, the momentum in that wave must also
be conserved.

> Numerologically it surely does appear that one can superpose powers
> since 200+(-50) is 150.

Superposition requires a phase angle and power has no phase
angle so superposition cannot apply.

However, in the complete absence of interference, powers
can certainly be added. In the irradiance equation, if the

interference term is zero, the sum of two powers is simply
P1 + P2. It happens when the two waves are normal to each
other.

Does a light wave from Alpha Centauri that never encounters
anything except free space transport energy? It certainly
depends upon your definition of "transport". It has an
E-field, a B-field, and a Poynting vector but is it
"transporting" energy if it never encounters a load to
which to transfer energy?

Nope. I don't think I will recognize that.
If you have resistance in an antenna circuit, the transmitter
is not going to magically make up for this loss by applying
an extra dose. That power is lost as heat forever, never to return
again as useful to Art RF energy.
This one simple fact blows your whole expectation of full size
performance from a tiny "gaussian" radiator theory full of 00
buckshot.
There is no free lunch. Even for aliens.

My logic is sound, but perhaps my statement was too brief to convey my meaning.

By smooth flow of power and energy from source to load, I do not mean a DC like flow. Instead, I mean that we should be able to trace the time slice that contains the peak energy level of any wave. The energy in this time slice MUST follow the rules of conservation of energy so it will not disappear. The flow of power and energy that I was speaking of is the physical movement of this slice of energy followed through time.

Your mention of energy flowing "in one direction during half the cycle and
energy flowing the other direction during the other half" would be in reference to a reflection from any source. My contention is that the reflected energy comes first from a source and is traceable to that source. In the case of lumped reactance, we can still trace the peak through time while recognizing that the physical location may not move during the time the peak is within the reactive component.

A reactive element can easily return the stored energy any time after the peak has passed, not waiting until the second half of the cycle. Therefore, your emphasis on "If the load is purely reactive, it stores the energy for half the cycle and returns it during the other half." is misleading. I think you want to more simply say something to the effect of "If the load is purely reactive, it stores the energy for some period of time before returning the energy".

Cecil,

There is at least partial progress.

You have quietly dropped the embarrassing confusion between phasors and field vectors. Unfortunately, you are still suffering from a problem in understanding ordinary English language. "Properties" is not the same as "requirements". The "requirements" are simply that Maxwell's equations are obeyed.

By the way, a standing wave meets at least 5 of those 7 properties.

snip

How is the word "moving" being used in this quote? Is it used as a
gerund meaning "causing to move" or as a participle describing energy
that is in motion?

I can accept that causing energy to move, as in accelerating charges
to launch an EM wave, requires work be done. And that the existence of
moving energy in an EM wave implies work was done at some previous
time.

But the mere movement of energy (say, in free space) does not seem to
involve work. If it does, is that work in addition to the work done to
launch the energy? Is the amount of work done per unit time (or
distance) constant?

It cannot be the work done by the moving-while-alternating E-field on
all the charges in the universe, since it is claimed that no energy is
being "dissipated."

Is some transformation of EM energy taking place?

TIA for any elucidation.

I can see that my question of how polarity changes on either side of a zero voltage point, and my example of a measurement accross the zero voltage point, did not shake your assumption that no energy crosses the zero voltage point. Having the assumption that energy does not pass the zero voltage point strikes at the heart of the traveling wave concept. I can not see what would reflect the waves to prevent energy passage at the zero voltage point, nor can I see a way to get the results we see between reflection points, if we disallow energy passage at zero voltage points.

> And when there are multiple reflections, there are multiple travelling

Yes. They merge if they are of one frequency, so tracing of multiple traveling waves is reduced to just the last forward and reflected wave. If the waves are of different frequency, they would each be traced by frequency.
>
> And even a standing wave has energy moving. Just not past the voltage
> and
> current zeroes.

Again, I would consider the traveling wave concept defeated if energy is not allowed to pass the zero voltage point. I think that the change of polarity on each side of the zero voltage point is a convincing argument that energy does pass. A change in measurement point to measure across the voltage point is also convincing to me, that energy must pass. I would hope that those arguments convince you as well.

Hi Chuck,

Your question is as about as free of the ongoing myopic failures as
any to come down the pike.

To put it in the terms of Feynman:
"If the force, for instance, is in one direction and the object
on which the force is working is displaced in a certain
direction, then ONLY THE COMPONENT OF FORCE IN THE
DIRECTION OF THE DISPLACEMENT does any work.
[emphasis in the original]
...
"The rule is 'force times distance,' but we really mean only
the component of force in the direction of the displacement
times delta s or, equivalently, the component of displacement
in the direction force times F. It is evident that no work
whatsoever is done by a force which is at right angles
to the displacement."

I have had the benefit of especially good and rigorous instruction in
Physics, and I have long noted the religious storms that have swirled
about the topic of "conservation of ____" (fill in the prayer book
blank). I have also long noted the complete absence of any actual
complete balance which necessarily requires both forms of energy,
kinetic and potential. In fact, kinetic energy has seemed to be the
uninvited guest to any discussion - treated as some poor relation
consigned to the oblivion of consideration.

If anyone is really pursuing the topic of fields and work, then they
should at least visit the authority on the topic, Feynman, and read
his chapters wholly devoted to the topic:
13 Work and Potential Energy (A)
and
14 Work and Potential Energy (conclusion)
and specifically:
14-5 Potentials and fields

I include chapter 13 because within it, in a subordinate almost
parenthetical aside, we find (on page 13-2) Power:

"Because the concepts of kinetic energy, and energy in
general, are so important, various names have been
given to the important terms in equations such as
these [referring to material preceding the statement].
Fï¿½v is called POWER:
the force acting on an object times the velocity of the
object (vector DOT product) is the power being delivered
to the object by that force. We thus have a marvelous
theorem: THE RATE OF CHANGE OF KINETIC ENERGY
OF AN OBJECT IS EQUAL TO THE POWER EXPENDED
BY THE FORCES ACTING ON IT."
[emphasis in the original]

Feynman is not generally available, but he is certainly held by many
of those stumbling over the terms of their own invention.

Attention all Amateur Operators.
Please Read, and send your comments to the ARRL and Romney Website.

Wednesday 16 November 2005 @ 15:48:10 | Eastern Massachusetts ARRL Romney 'Disses' Amateur Radio In
Televised Town Meeting Posted on Wednesday16 November 2005 @ 15:48:10

Governor Mitt Romney dismissed the role of Amateur Radio operators in emergency communications
during a televised 'town meeting' program last night on WCVB's 'When Disaster Strikes: Segment Two.'
The program featured public safety and volunteer organization officials from
across Massachusetts
among its audience.

Host and moderator Natalie Jacobson asked an increasingly-agitated Governor Romney questions about
communications interoperability, and communication without commercial power.
Romney was next asked
by Jacobson, '...so does it come down to ham radio?...'

The Governor replied in a disgusted tone, 'No, we don't need to deal with ham radio operators...'

Embarrassed public safety officials later tried to put in a good word for Amateur Radio. National
Weather Service Warning Coordination Meteorologist Glenn Field was prepared to state the importance
of Amateur Radio, when Salvation Army Colonel Fred Van Brunt was called upon. Van Brunt remarked
about his organization's quest to improve its communications capabilities and how Amateur Radio has
aided his organization. 'The ham radio situation helps a great deal,' he stated.

'I have already written and submitted a letter to the Governor's Office,' wrote Eastern MA Section
Emergency Coordinator Rob Macedo, KD1CY. 'I have also written an email to Natalie Jacobson.'

ARRL Section Manager Mike Neilsen, W1MPN sent a section-wide email today to all Eastern MA ARRL
members describing the incident along with actions he and his staff were taking to mitigate the
situation.

'[Romney's] attitude about us sets an unfortunate tone within the state's executive branch,' wrote
Neilsen. 'As a former military officer, I see this as a failure in leadership. My immediate concern
is our working relationship within the [Massachusetts Emergency Management Team] environment.'
Neilsen intends to address the Governor's comments as 'an urgent matter' at a meeting on November 17
with Don Carlton from the Massachusetts Emergency Management Agency.

'I was very disturbed about what the Governor stated on the program,' wrote Ron Wood, W1PLW, the
section's Public Information Coordinator. 'It does show that more work is needed by all hams in the
section. It's a great idea to write letters explaining the good we do.' Wood
is attempting to
schedule a meeting with the Governor's office tomorrow so that EMA ARRL staffers might discuss the
matter further.

Tom Kinahan, N1CPE wrote that Governor Romney's comment has made 'a PR problem' for Kinahan in his
role as MA State RACES Officer.

'I've got a roster of over 150 Amateur Radio operators that support local communities, and those of
us that directly support the state government. There are at least double that in terms of people
that are actually out there that I don't have formal paperwork on that support Amateur Radio
emergency communications in some organized manner... The Governor has said that he 'certainly
doesn't need to rely on ham radio' -- where does that leave the RACES program now?'

'I am ashamed tonight that I am a Republican!' remarked one ham radio viewer. '[Romney] speaks in
derogatory tones about hams. He certainly shows an ignorance as to what we do and are capable of. I
suggest a grass roots campaign of local hams calling the State House and The
Governor's Office to
protest.'

But as I said, there is no energy where there are no waves, so the
sentence makes no sense. There is no "energy in canceled waves".

One more good reason not to vote for him...but look at the bright side: This will give him a chance to flip-flop again and say how much he likes hams. ;-)

P.S. Even though I'm not a resident of the state of Massachusetts, I wrote a letter of protest at the time. As a non-resident, you can imagine how far it got.

That is certainly one avenue to pursue; however, some roads lead to
better places than others.

How about a re-evaluation of us, our plans, our equip., etc. and instead
of finding fault with other--why they do not find our services
desirable, we ask the question, "What can we do to become
up-to-date-current and make our services desirable--to the point they
can't ignore us?"

But then, that stands a fat chance ...

Regards,
JS

>> total electric and magnetic field strengths. [end quote]
>>
>> A standing wave doesn't satisfy any of those properties.
>
> By the way, a standing wave meets at least 5 of those 7 properties.

1. A standing wave doesn't propagate.

From "Optics", by Hecht. "[A standing wave] doesn't rotate at
all, and the resultant wave it represents doesn't progress
through space -"

2. A standing wave doesn't propagate.

3. The electric field is either 0 or 180 degrees apart from the
magnetic field. I proved that with math equations in an earlier
posting which I invited you to disprove and you declined. Hint:
see R&W quote below. The pure standing wave Poynting vector is
known to be zero. The only way for that to happen (when E and H
are both not zero) is for the E and H vectors to be mutually
parallel, i.e. 0 or 180 degrees apart.

4. The ratio of electric field to magnetic field is not constant
so it cannot be equal to the intrinsic impedance of the medium.

5. A standing wave doesn't propagate.

6. At any instant, at a point, all the energy may be stored in
either electric or magnetic field while the other is zero. At
the nodes, energy is never stored in one of the fields.

7. At a point where E=0, H will sometimes be maximum. Again,
the intrinsic impedance is not the ratio of E to H.

Sorry, 0 for 7. A standing wave is NOT a uniform plane wave.
As Hecht said, it is questionable whether a standing wave
deserves to be called a wave.

Also from Ramo & Whinnery:
"It is also instructive to consider the cases for
which there will be no power flow through the electromagnetic
field. Accepting the foregoing interpretation of the Poynting
vector, we see it will be zero when either the E-field or
H-field is zero, or when the two vectors are mutually
parallel." see item 3 above.

In the case of a radiator, the emanating energy is a result of the
superposition of fields radiated by the currents traveling on the
antenna. I could be mistaken, but it seems to me that superposition
should yield the same result by either approach. If so, then for a
single element radiator, the field pattern would appear as though a
standing wave on the antenna had created the field.

The medium at the zero voltage point is homogeneous.
Nobody has produced a reference for or example of
reflections occurring in a homogeneous medium. Until
such evidence is introduced, it is probably safe to
assume that reflections in a homogeneous medium in
the real world are impossible (except in a human
mind where anything is possible).

>
> Best regards, Richard H. Harrison. KB5WZI

In my copy of Bailey (1950), he says (p. 415) that the feedpoint resistance of this antenna at resonance is very high, its value depending on the conductor diameter and spacing. He shows one example having a resistance of 4160 ohms, and states (p. 416) that

"Thus we see that at first resonance the [quarter wavelength] folded dipole exhibits the qualities of a shunt-tuned circuit and has a terminal resistance value Ra of high magnitude. This precludes its general use where a normal transmission line is employed, unless the rods are made very thick."

Even if you did manage to reasonably match the antenna, the bandwidth would be very narrow and the loss potentially high.

Sorry, as Robert Heinlein said, TANSTAAFL - There Ain't No Such Thing As A Free Lunch.

The field created by any conductor is proportional to the current flowing on the conductor. You can divide this current into "forward" and "reverse" waves, or any combination of currents you want, just as long as they all add up to the total current. Assuming the conductor is immersed in a linear medium (e.g., air), you'll get exactly the same result by finding the fields from each of the individual currents you've chosen and adding them together, as you will by adding the currents first to get the total current and finding the field it creates. That's an example of the application of superposition.

There existed energy in the two waves before they were canceled.
Their ExH Poynting vectors had equal magnitudes and direction.
Their phases were opposite and they canceled. Their energy
components cannot be canceled or annihilated so the energy
is redistributed in the only other direction available. Exactly
what is it about the FSU web page that you do not understand?

Concerning the reflected wave cancellation process at a non-
reflective 1/4WL thin-film coating:

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

From Ramo & Whinnery, Page 440: Waveguides - Elimination
of Reflections from Dielectric Slabs.

"For slabs of any thickness, reflections may be eliminated
by canceling the reflected wave from one slab by that from
another placed a proper distance from it."

Before wave cancellation, the two waves contained energy.
After cancellation, they ceased to exist in their original
direction of travel. Energy cannot cease to exist so it
has to go somewhere. This is not rocket science.

You have tied yourself into a Gordian Knot. If there is
no canceled wave energy to redistribute, then there were
no reflected waves to begin with and the anti-reflective

coating was completely unnecessary. Peel it off and see
what happens.

On a 1/2WL dipole, for instance, of the total amount of
average energy existing on the antenna, approximately
80% of that energy is in the standing wave. The other
20% is radiated as real power presumably from the traveling
waves because standing waves contain no real power. Like
impedance transformation on a transmission line with
reflections, the standing wave on the dipole is used
to transform the relatively high Z0 of the antenna wire
down to the relatively low feedpoint impedance of the
antenna. The source re-supplies the radiated power to
keep the average standing wave energy constant.

Since the standing wave energy is being used to transform
impedances, it cannot also be used for radiation purposes -
like the energy in a standing wave on a transmission line
cannot be used both to transform impedances and to heat
up a load.

Wave cancellation is a continuous steady-state process.
Every instant of present time, reflected waves are in
the process of being canceled. The power density equation,

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(A)

is a continuous steady-state process.

The s-parameter equation, b1 = s11*a1 + s12*a2, is a
continuous steady-state process. If you square both
sides of the equation you get the power density equation
above. IT IS A CONTINUOUS STEADY-STATE PROCESS that
spans the past, present, and future until the power
down transient state begins.

Hi Ian. Yes I've seen that page. However I'm constrained not so much by
capacitor values and ratings as by the size of an existing box it goes
into. Now I'm retired I don't have access any more to "metal bashing"
facilities as I did and it would be much easier to use an existing box
which is 115mm high, 200mm f/b and 300mm wide.
I sold my original Z match some years ago which tuned very well and
built this one with some very nice silverplated copper tube coil stock
which I had around at the time. Unfortunately I'm not very confident
that the coils which are nearly 90 mm diam overall aren't being
excessively affected by the closeness of the metal chassis.
Fortunately I have an LCR bridge which measures down to uHenries
so I will measure up the coils again and check for resonance.
The tuning is done with a twin gang 210 pF max Tx cap from a pre WW2
TX with some of the lossy dielectric replaced and the coupling cap to
the TX is a 1950's beefy 500pF TX type well insulated from earth.
With my current G5RV I find that the tuning is VERY critical and the
matchng on 80M is with rather too low a tuning cap value.
So as you see it would be reassuring to have actual indiuctor values in
u Henries to work with so as to determine which size and type of coil
will best suit my purpose.
BTW I run about 200W max with an old Kenwood 820s at the moment.
73's Cliff Wright.

but you can neither create nor destroy energy, so it can't just be
'canceled' it has to be either converted to some other form of energy or go
somewhere else... it can't just disappear.

> And I do not mind this definition.

That was probably a bad choice of words on my part. By net I didn't mean an average over some period of time. I meant energy moving past a single point.

One possibility I envisioned was some energy moving past the point from left to right, and at the same time an equal amount moving at the same rate past the point from right to left, resulting in zero power at the point. However, on reflection, this couldn't happen; energy flows "downhill". But the phenomenon observed on the open circuited line does occur, where energy flows into the point from both directions equally, and out of the point to both directions equally, resulting in zero power at the point. No energy is flowing past the point, period -- the modifier "net" isn't necessary.

You're right. Please consider "net" retracted.

If the power source is disconnected from the SW in an ohmic-lossless antenna in free space, then the standing wave gradually collapses. One could think of the collapse as the gradual attenuation of the forward and reverse EM waves radiating out of the antenna as they reflect back and forth. One need not consider the standing wave anymore; one woukld better think of the individual Vfor and Vrev components as they radiate and the SW collapses to zero.

Hi Rich:

The force in the direction of the displacement must also overcome the normal force times the coefficient of friction. Since the normal force is at right angles to the displacement, the wording in your statement above may need some modification such as:

"... the component of force in the direction of the displacement, including normal forces at 90 degrees to the displacement which causes a frictional force, as determined by static and dynamic friction coefficients, occurring in the opposite direction of the displacement, that must be overcome".

954. Loop antenna question????

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-16 23:55:12 UTC
From: WA4SZE@gmail.com
Message-ID: <95e51d2f-140b-4e6d-828f-d6dd4f43014f@j78g2000hsd.googlegroups.com>
Source record: 29420

Greetings!

I picked up 2 Alford loop antennas from a ham fest. The antenna(s) is for 112 mhz The data plate states VOR antenna 50 ohms. The antenna(s) has Three N connectors one is to feed the RF from the transmitter the other two are connected with a 31.5 inch length of RG-214 coax. (the 31.5 inch coax came with the loops)

I looked in the ARRL antenna hand book and it looks like the loop of coax is configured as a 4 to 1 step up Balun??? The ARRL hand book states that the Coax loop should be a electrical half wave of coax : The coax loop is about 5 inches short of 1/2 wave at 112 mhz

When I hook up my MFJ-269 I get the following:

Freq: 112 mhz

RS - 9

XS - 68

Impedance : 95 ohms

VSWR 14.8 ????????

both loops have about the same readings!

WHY??? They are stamped with 50 ohms ?? but they don't measure out to the data plate??
Can the length of the Balun loop have effect on the VSWR of the loops

What do the MFJ-269 readings tell you

Thanks!!!!!
Dave

> of that point, is any energy transferred?
>
> The answer is - of course - equal amounts in either
> direction.

So you seem to be claiming that the following two
statements can be simultaneously true:

1. Power [recall p(t)=v(t)*i(t)] is the rate at
which energy is transferred.
2. Energy can be transferred when the power is zero.

To my simple intellect, one of these statements
must be false.

==========

The statements need some work:

1. Power (in watts) [recall Preal = v(t)*i(t)*cos(theta)] is the rate at
which REAL energy is transferred where theta equals the phase angle between
REAL power and reactice power. Reactive/Stored/Imaginary VAR power =
Preactive = v(t)*i(t)*sin(theta).

2. Energy can be transferred when the REAL power component is zero, or, when
the REACTIVE power component is zero, but enregy CANNOT be transferred when
both the REAL and REACTIVE power components are zero.

> Would you care to elaborate on the idea that "energy is being used to
> transform impedances"?

If reflections are nonexistent, no transformation takes
place, i.e. there is no SWR circle, just a point at the
center of the Smith Chart and the system is flat.

If reflections exist, then the superposition of the
forward wave and reflected wave transforms the
load impedance to some other impedance on the SWR
circle.

A 1/4WL transformer, for instance, will not transform
unless there are reflections present.

Either energy flows past the point or else it is reflected.
Please provide an example of reflections occurring in a
homogeneous medium.

Yes, we want the reflections to be continuously canceled
in real time and for the reflected energy to be redistributed
back toward the load in real time.

The second statement is an oversimplification - it switches between two inconsistent sets of boundaries. Energy is being transferred within the system as a whole, even though the power p(t) at some individual points within the system is zero. If you look consistently at the system as a whole, there are no contradictions.

```
-----BEGIN PGP SIGNED MESSAGE-----
Hash: SHA1

I saw this 50 ohm "terminator" BNC connector at Radio Shack today and
was wondering if it could be used as an antenna dummy load? It is
designed as a computer network terminator - just a female jack without
any output connector. I believe the only question would be "Could it
stand the power output?" What if the output was just 5W? Anybody know
about this product or have used it as a dummy load?

It'd sure save the price of a "real" dummy antenna (it was priced about
$4.00 USD).

Thanks

Hello, and I've got a whole box of these in my networking lab (from the
old 10Base2 days). A terminator certainly could be used as a dummy load
but I would probably keep the average RF power delivered it under 1 W.
Not sure how useful that would be even for a QRP setup. Sincerely, and

> whole, there are no contradictions.

Expanding on statement 1) from above....
p(t) = v(t) * i(t)
computes the power moving between two networks
separated by the point at which v and i are
measured.

Expanding on statement 2...
Cecil's claim is that the "energy in" the
forward and reflected waves travel from end
to end on the transmission line.

Applying statement 1) to any point on an open
circuited transmission line where the current
or voltage is always 0 will yield a power that
is always 0.

Applying statement 2) to this same point yields
that energy is crossing this point.

This seems to me to be a definite contradiction
between 1) and 2) for the specific situation under
consideration.

...Keith

Almost certainly, the power rating of the terminator is either 1/8, 1/4, or
1/2 W.

> to end on the transmission line.

The forward wave and reflected wave each possess energy and momentum which must be conserved. Assuming the transmission line is a homogeneous medium, i.e. a constant Z0, there is nothing anywhere along the line that can possibly cause a reflection. A reflection is necessary to reverse the momentum of a wave and reflections are impossible in a homogeneous medium. By the process of elimination, there must be something wrong with statement #1.

This is easy to demonstrate on the bench using a TV signal. Even though there are points of zero power in the standing wave, ghosting will be clearly visible proving that the forward wave has made a round trip to the end of the stub and back.

The superposition principle allows us to analyze the forward wave and reflected wave separately. When we do that, it is obvious that energy is flowing both ways across that zero power node location and at all other points on the line. If the reflected wave is equal in magnitude to the forward wave, the net power is zero at every point on the line, not just at the nodes. The Poynting vector for the forward wave is equal in magnitude and opposite in direction to the Poynting vector for the reflected wave.

Oops, I am afraid I must retract my previous congratulatory progress report. You are obviously still confusing phasors with field vectors. Until you get that terrible misconception sorted out, there is no hope for further progress.

I assume that Hecht covers the equations and such. I am sure that Born and Wolf cover this subject in detail. Check out page 277 in the 6th edition or page 308 in the 7th edition. You will quickly observe that the H-field is always perpendicular (90 degrees) to the E-field, even for standing waves. There is no "0 or 180 degrees" involved.

Is there anything else you plan to teach me about physics? There is still a whole lot I don't know. I think I may seek out another source, however.

Cecil'
How can one focus so long on travelling and standing waves when the
radiation portion
of the subject has not been explained? If waves is the subject it
cannot be discussed coherently if you cannot describe the mechanism of

radiation, and that subject is inexplicitely bound up with this whole discussion. All of this is pure conjecture based on what is happening behind a closed door which cannot continue until that door is opened. Only then will this discussion be revealed for what it truely is, which is all the things that could be happenning where the winner, if there is one,will be picked when the door is finally opened. Until then every thing is pure guess work.
Best regards
Art

> for further progress.

Let's skip your objection for the moment and let you
answer this simple technical question.

Poynting vector = ExH = E*H*sin(A)

The Poynting vector for a pure standing wave = 0.

It is always zero even when both E and H are not zero.

So here is the question for you. Assuming that neither
E nor H is equal to zero:

When E*H*sin(A) = 0 (Poynting vector)

What are the possible magnitudes of angle 'A'?

This is a simple technical question having absolutely
nothing to do with confusing phasors with field vectors.

Please provide an answer.

> I assume that Hecht covers the equations and such.

Yes he does. He also recognizes when the EH fields
incident upon a plane can be validly represented by
phasors. Apparently, Hecht also "confuses phasors
with field vectors". (SIC)

The mechanism of radiation is pretty simple from a quantum
electrodynamic standpoint. Accelerated electrons emit
photons. Some of the photons escape the antenna. The
energy lost by the escaping photons must be replaced
by the source. QED. :-)

Art, if you would replace electrons with photons in
your blast-off theory, you will be closer to the facts.

Draw a plane through which a plane EM wave is passing
normal to the plane. Now please explain exactly why
the E-field and H-field cannot be represented by
phasors.

I posted this separately to keep from confusing simple
issues with complex issues. Get it? Complex issues? :-)

Thank you for your civil reply.
What I am trying to say is that this long long thread has got a life of its own that it is excluding a lot of people. If it concentrated on say, a simple parallel circuit, a very simple circuit then the absolute physics of what is being discussed would be an immense help in explaining this wave discussion.ARRL states that an antenna is a simple parallel circuit but this concentration on antenna workings is blind siding every body as well as providing a means for twisting the discussion because the makings of radiation is not known.
Why not illustrate waves in a simple parallel circuit so that observers can partake in this discussion which, if it ever comes to closure, could then be used to demonstrate their effect on radiation?
Onlookers are more than willing to partake in the discussion but presently they are on the side lines because as presented it is limited to only those whose intent is to argue without obtaining closure and their feeding habits are insatiable as you are finding out.
Best regards
Art Unwin KB9MZ......XG

Incorrect. The Poynting vector is defined as E x H*. The vector directions are critically important. It is absolutely incorrect to try to reduce to some scalar type equation. (The '*' means complex conjugate, but this detail is not always important.)

>
> The Poynting vector for a pure standing wave = 0.

Says who? Perhaps the time and space averages or "net", whatever that means, but not the local instantaneous Poynting vector.

>
> It is always zero even when both E and H are not zero.

Nonsense. It is E x H* at every point. If E or H is zero then the Poynting vector is zero. Otherwise it will not be zero.

The answer is that you have started with incorrect equations.

>

You have obviously misunderstood what Hecht is saying. A phasor does not carry any vector information. It is a representation of magnitude and phase angle only. That says absolutely nothing about the direction of the field vector. The phase angle is completely unrelated to the vector direction of the E-field and/or H-field.

Cecil,

The phasor has nothing to do with spatial direction of the field vector. It has everything to do with the amplitude and the (wt-kx) term in the wave equation. (The 'x' is simply a distance measure in the propagation direction. It does not say anything about the field vector directions, since the fields are transverse to the propagation direction.)

This is really, really basic E&M stuff. If you still disagree, then you are own your own.

This discussion, to a large extent, is concerned with the
nature of RF waves. There are no RF waves in a simple
parallel circuit. I posted a list of characteristics
of an EM plane wave. A parallel circuit doesn't match
those characteristics.

Those who don't remember what the cross product is,
please reference:

http://en.wikipedia.org/wiki/Cross_product

Another name for the cross product is the vector product.

Quoting "Fields and Waves ..." by Ramo & Whinnery:

Poynting vector = ExH These are, of course, vectors.

Quoting "Reference Data for Radio Engineers":

ExH is called the Poynting vector. Again, vectors.

The average Poynting vector is defined as
Re(E x H*)/2 in my references.

So your "Incorrect." assertion above is proven to
be incorrect.

>> The Poynting vector for a pure standing wave = 0.
>
> Says who? Perhaps the time and space averages or "net", whatever that
> means, but not the local instantaneous Poynting vector.

Let's deal with the average Poynting vector. The real
power in the fields is equal to the magnitude of the
average Poynting vector. There is zero real power in
the standing waves. Therefore, the average Poynting
vector is zero at every point on a line containing
pure standing waves.

So, using Occam's razor, here's the same question
for you stated in a different way.

If E and H* are both non-zero, how can the following equation
be equal to zero all up and down the line as we know it is for
standing waves?

Pav = Re(E x H*)/2 = 0 where E <> 0 <> H*

>> It is always zero even when both E and H are not zero.
>
> Nonsense. It is E x H* at every point. If E or H is zero then the
> Poynting vector is zero. Otherwise it will not be zero.

True for a uniform plane wave. But I have already proved
that a standing wave is not a uniform plane wave.
Pav = Re(E x H*)/2 = zero for a standing wave. I hope
you don't question that fact of physics.

> The answer is that you have started with incorrect equations.

The answer is exactly what you have been missing. Please
solve the updated problem above.

It is obvious that if V*I*cos(A) = 0, then Re(E x H*)/2
must also be zero even when E and H* are not zero. How
do you explain that fact?

The E-field and H-field of an EM wave can certainly
be represented as an exponential function when the
EM wave is normal to the reference plane. Think
about it. Hecht used that feature in his book.

> simple parallel circuit

Here is my civil response: For this discussion there is little benefit
in using lumped component theory. The standing wave stores energy in
an antenna in a manner similar to energy stored in an inductor and a
capacitor in a resonant component circuit but it is not very useful to
use lumped components when explaining why a standing wave cannot be
used to measure delay in a coil, for example.

Further questions that challenge your (and the ARRL's) simplified
model:

Is the resonant circuit dependent on the capacitance and inductance of
the antenna or its length?

If your answer is "both", (which it is), why does it happen to be
both?

Why does 1/4WL of the length of the antenna just happen to be a
resonant point of the capacitance (in x _farads) and inductance (in y-
henries) of the antenna?

Why physically is that so? Nature is telling you something there.

You should understand that concept well before you get to the
radiation of particles (and they WILL be photons).

With getting all the politics.

Romney just lost my VOTE. I have been a ham for 35+ years and working in emergency services for over 45 years he is a looser. NO, I will not vote for McCain either, and I'm a proud VETERAN.

Cecil:

If you do nothing else, check out this youtube link:

http://youtube.com/watch?v=s08RJ2_o_MM

A man with a rational mind does much to restore faith in America. He speaks of the "insanity" running rampant in America ...

Better yet, use the search on the youtube page and search for all the vid clips on Ron Paul.

Regards,
JS

well, it would either be bought by paranoid anti-electromagnetic field
idiots with more money than brains. or industrial safety engineers who have
to verify field strengths from intentional radiators are under the fcc or
other government exposure limits.

Cecil
But I am not sure they understand one bit of what you are proposing!
With respect to your remark on my radiation attempts.
When this group did not understand the relevance of Gaussian equation
with those of Maxwell
I decided to dumb it down and refer only to particles. Later I was
forced to move up to electrons because of counter posting. If I was to
move now up to protons when the group does not understand electrons or
even the common parallel circuit I think I would then parallel your
situation where you refuse to dummy down to reflect the audience.
Thisd would then mean a continuum of postings that would only go
around in circles becaus of their past cessation in learning.
Best regards
Art

There are a host of applications that simply cannot be dummied
down to the lumped circuit level. I am unable to teach my dog
to look at the clock and tell whether it is dinnertime or not.
Is that my fault or hers? The answer is more complicated than
one might think at first glance.

Cecil,
I respectfully do not agree with that.I would suggest that the antenna
mechanics what I am preaching is directly applicable to complex
circuitry.If antenna theory can't
apply to such then the theory is in error.Antenna radiation came to a
halt in understanding some 50+ years ago.Since then science have tried
a lot of new sciences that even tho they do not solve the mystery of
radiation provides a whole new stream of old wives tales.And hams are
sucking every thing up without question. Nature has simple habits , it
is humans that try to make it complicated.
My best regards
Art Unwin KB9MZ...XG (uk)

You're not firing on all cylinders tonight, are you? My question, is since it wasn't originally posted in all these groups, why the last moron, felt it was necessary to suddenly cross-post his response to everyone.

As others have noted, beware of the power rating. On the other hand,
I have a dummy-load-on-BNC-jack that I made with four 200 ohm 2 watt
metal-oxide resistors (and the connector, of course). The connector
is one with a square base, four ground pins and a pin in the center,
for mounting on a PC board, like DigiKey A24512-ND. I cut the lead
completely off one end of each resistor, and trimmed the lead at the
other end of each so when folded over back against the body it reached
not quite all the way to the end with the lead cut off. The four
leads are soldered around the center pin of the connector. The
insulating covering is scraped off the resistor ends with no lead,
exposing the metal cup that contacts the resistive element. The four
ground pins are clipped off the connector, and the cups are soldered
directly to the connector ground, one in each corner. The result on
my HP8753E network analyzer (freshly calibrated and all that) shows
return loss greater than 40dB (S11 below -40dB) out to beyond 300MHz,

and greater than 20dB to about 850MHz. In other words, it is as good as my semi-precision loads out to 300MHz, and quite a bit better than a whole bunch of other 50 ohm BNC loads I have -- quite adequate for any ham work I would do out to 500MHz at least, and able to dissipate a moderate amount of power. YMMV, of course, depending on the particular metal-oxide resistors you use, and admittedly it is really helpful to have a good network analyzer around to test it on. But it should be no problem making a load that way, usable through at least VHF.

Cheers,
Tom

OK art, I notice a great improvement in your having only 3 spelling errors in 5 sentences. You are a fool. If your postings could ever be elevated to the level of mere stupidity, then it might be possible to correct your misconceptions. However, one cannot deal with true insanity by any rational approach such as that. You do not drive me to use Google; you drive me to dictionary.com so I can find the words appropriate to describe the idiocy of your ravings. However, it isn't worth the effort so I will leave you mired in your intellectual wasteland, reading your postings from time to time for the entertainment value of comic relief. For the sake of the hobby I will continue point out the fairy-tale nature of your postings lest the casual reader of this newsgroup ever get the wrong impression of what the typical ham radio operator thinks is antenna "theory".

For entertainment value look for where the photon term came
from.....Quantum theory
which has not been proven. If a particle os in a magnetic field it can
take on some of the properties of that field. To be propelled requires
mass as does a mechanical vibration of a radiator. Yes mechanical laws
equate with electrical laws.The object that was repelled is a mass
with anti gravitational tendencies which allows it to have straight
line trajectory.
That straight line trajectory is of a partical that now has potential
energy received from a magnetic field. That energy becomes Kinetic
energy on impact with a receiving antenna which thus is instrumental
with a multitude of other particles in applying a mechanical force
whose reaction is supplied by the receiving radiator in the form of
vibration. When you are talking radio you are talking MHz which
translates into millions of particles or samples taken by the
receiving antenna, a lot more than your ear can accomplish. The proton
idea was thought up by Einstein in an effort to understand what
radiation is and he died without solving that puzzle.

Einstein made a tremendous amounts of errors in his life time and this is just one of them.
Ham's look for resonance has the salvation of all but this is just a ham's point of view. Like a quadratic equation there are two answers to choose from, but only one that satisfies Newtons requirement for equilibrium. Ham's choose to recognise just resonance because it is self serving for amateur operation,but science will always follow the requirement for equilibrium
just as all the masters did.So many new sciences were invented in an effort to identify radiation that were not required because the simplicity Of Gaussian law reflected the true nature of radiation.
You have called me a liar and a fool but are not willing to raise a few thousand dollars to prove that I do not have a 160M antenna on the top of my tower, that I am a fool and a liar Money is waiting for you and your backers just by y showing I do not have a 160M antenna sitting on my tower. You have some gall to call me names and then backslide when asked to prove your point.
No, I am not going to insult you, your own actions show what manner of man you are.

You know. that statement was made a decade ago by W7EL and he started
up a storm of auguements
on this newsgroup which pushed off so many knoweledgable engineers/
radio hams. Problem was that W7EL choose hismelf as the adjudicator as
what is right and what was wrong! Knoweledgable did not always agree
with W7EL but with the diatribes thrown they choose to leave. Now you
also have chosen to be the adjudicator in conjunction with W7EL!
Give me a break.

Art is entitled to his opinions which are no more crazy than, say,
Christian dominionism, or "creation science." They may be wrong and
hard to make sense of, but at least they're honest and
original.

I dout they have a power rating on Digital line terminators! That isn't
one of the specs in common use in that field.

They aren't made for terminating much power at all.

As for the original question, they can be used as a terminator, but not
at the power levels we are likely to use, unless you are into QRPp.

Art, I've asked you to provide information on your 160m antenna twice previously. You referred me to an eham tower of babel after the first and responded something about not operating on 160 for the second.

I'll ask you for the third time: Would you explain your 160m antenna for us? Do you believe it to be as good or better than a full-sized inverted L over an extensive radial field? Have I wasted time, effort and money in installing my inverted L when an 18 foot antenna would have done the same job?

If they are wrong, they aren't honest. They're simply bad science and not worthy of our time. One of Art's biggest problems is that he writes in kooky generalities and never ever provides specifics. I've asked him three times for information on his 18 foot 160m antenna. All I've gotten in response is a bad tap dance.

I have no choice but to put him down as a lonely old eccentric, a few degrees off level.

Dave,
Over the years many have asked that same question and I have answered
it many times.
When ever a newbie comes along they always ask the same question
without looking back at my past posts since they want to argue. Now it
is you who is starting the post with a caustic comment regarding the
"tower of Babel" but at no time have you or any newbie initiated a
discussion before making a insult to follow the crowd. What do you
think I should do when you call my writing "babel"? Now the computor
programs state that a tilted element provides more horizontal gain
than a horizontal element. This was followed up independently on this
newsgroup.No debate regarding the coroberation
So should we all dump the antenna computor programs? Many hams say
they did this or did that and produced better than sliced bread. Hams
respond that you didn't measure on the range properly so give me the
math. I started off with the math which was corroberated by a doctor
working for a space agency. Guess what? He got plastered for "poor"
mathematics.
This group cannot debate any thing which is why only a few dominate
the group now. Past experts have left!So I ask you"how should this

group be run"?
Art

Sorry, but The IEEE Dictionary disagrees with you.
In the description of the Poynting vector, it says:
"E and H are the electric and magnetic field vectors
in phasor notation ..."

I have prepared a graph of a snapshot in time of
a forward wave and reflected wave of equal magnitudes.
When the waves are superposed at the reference plane,
the total E-field and total H-field are 180 degrees
out of phase. The graph is at:

Yes, but all that is probably just a factor/side-effect of the special classes he which he was "initiated" with.

You'd be better looking for more "intellectual fields" to plant your ideas in ...

Why are you asking me all these questions?
Can't you read a book?
Why not ask an expert on Eham and then come back
armed for an arguement. At the moment you are un armed
and defenceless. By the way the money is still out there.
It is not such a large amount but it will pay for lunch
while you crow about proving me a liar or you could be crying
about how you were dethroned instead. T'was you who made
that foolish statement in the first place. Somebody stated
that they had a 160M antenna on the top of their tower which
isaparently is rediculous. Now a small amount of money is

being mentioned and now you have second thoughts.
A 160M antenna is crazy for those who believe all is known about
antennas
and you perceive yourself as an expert.What are you waiting
for,chicken wings?

I can only offer a couple of guesses.

Possibly the antenna is intended for receiving rather than transmitting. If that's the case, then the mismatch isn't as serious as for transmitting, although it would cause about a 6.5 dB signal loss compared to a matched antenna if connected directly to a 50 ohm receiver.

The impedances and SWR you quote aren't quite consistent. 9 + j68 ohms has an impedance magnitude of about 69 ohms, not 95. And it would result in an SWR of 15.95, not 14.8, on a 50 ohm transmission line. The MFJ calculates these from each other, so I have no explanation why you'd see contradictory values like that.

I can't comment on the balun setup except to say that the length of the transmission line loop is likely to have a significant effect on the antenna impedance.

Hi..

I wish to build shorty dipoles for 20 and 80 meters and have considered coil loaded but dismissed them as too narrow band so i`m considering linear loading
for b/width and space ...(my garden is 14ft x 35ft)...

I find my homebrew magloops r/x very well but don`t t/x too good!!! hence the need for a larger directional ant on the rotator without encroaching on neighbours space ....(too much) .... ;o)

I have googled, but there isn`t much info available and what there is, is a little
too technical for me to take in.. :o/

Is anyone familiar with the merits (or otherwise) + information and s/ware for
designing and building said antennae ?? all help and pointers welcome.

Thanks..

Len....G6ZSG.....

"Judge not lest ye be judged"

I come here to learn and converse with others of similar interests. Unfortunately, the atmosphere here is very hostile and uninviting. Who the hell wants to argue all of the time? Not me.

Many of you are far more educated than I, but many of you demonstrate precisely why I chose not to be brainwashed with a formal education. Many cannot see past the end of their noses, yet they insist upon laying down the law regarding what is acceptable science and what is not. As though anyone actually knows anything at all.

Each and every day there are new announcements that reshape our scientific paradigm. Who can keep up? It was while I was trying to keep up that I finally realized that the more we learn, the more we should realize that nothing is certain. Yet the same young/old coots are in here argueing day after day that what they learned in the 1940's and 50's, 60's, 70's, 80's, 90's and now the 20's, is the Gospel Truth. I wish you could see just how silly you appear to others. I'm not pointing the finger at anyone in particular.

Let's not forget that one's educational level has nothing to do with native IQ.

I think you know that I meant the magnitudes only,
but to be entirely technically correct it should
have been:

Poynting vector = ExH = |E|*|H|*sin(A)

The same question remains: When E and H are both
not zero, how can the Poynting vector be zero?

It's not ignorance - he's clearly in Motorola's back pocket, to take away whatever ham spectrum he can to give to the big communications cartels. All in the name of "emergency response", of course, but anyone who can add up a couple bandwidths knows that the real need is to give it to the cellphone companies.

The ARRL has to kind of pussyfoot around these issues because you can't have hams being against the communications cartels as long as "emergency responder radio" spectrum is their trump card.

LEE.
First get a hoola hoop from ASDA or a hose pipewith which you can make your own

Get a similar diameter former and wind wire on it close wound first in one direction and then reverse the windings on top of the first windings. Slide this on the hula hoop and then stretch it out like a fish net. The length of the wire must equal or exceed the wave length of the frequency required. You have two wire ends at the same point with which you can supply power. The wound wire is infact a loop circuit of its own and you can stretch it out using a MFJ 259 until you hit the sweet spot. Impedance will be around 20+ ohms which increases with the number of wavelengths used Note that the inductance is cancelled by the reverse turns and the capacitance is cancelled by the cross winding.Tho the antenna covers little area apurture is covered by gain, the loop with its inherrant gapaqcitive positioning creates an electric field that extends beyond its physical shape. You see this effect in a mobile when the audio increases as you drive by power lines and the like.
Cheers and beers

David, your denial of the mathematics of adding a time varying field
to Gaussian law to make it equal to Maxwell's laws doesn't make it

change. The mathematics is there, but since you can't handle integrals you chose to deny it and accuse others of poor mathematics.I don't know where you got your mathematics teachings other than it was probably in the U.S.Let me assure you once again, the mathematics is sound, the doctor from MIT made the mathematical steps very clear to all on the group yet this group, including you, denied the integrity of the math.
The results from new math is inherrently the same as old mathematics and your BS does not cancel that fact, even tho the group followed you into that same pit.
Have a happy day.

More likely it is due to the collection and re-radiation of fields by nearby conductors, so as to increase the net field arriving at the mobile antenna.

it is not unusal for the transmiters at an airport to produce a huge
amount of interrmod. This is because you may have a dozen or more
transmitters all keying at once and their antennas are closely spaced
often only 4 to 6 ft apart. This is not usally a problem for air
traffic control because the receivers are remotely located from the

transmitters often a mile or more separating the two. On the occasion this is a problem circulators are placed on the transmitters to eliminate the intermod'

If you are a good distance from the tx site and are still experiencing an intermod probllem it is because the mixing action is taking place in your rx in instead of the transmitters.

Known by whom?

If you are talking about time and/or spatial averages then yes, the
Poynting vector will be zero. If you are talking about instantaneous
calculations at any point and time, then no, the Poynting vector will
not be zero all up and down the line.

Once again you have misinterpreted something you read in a book.

The graph is complete nonsense. There is no rotation of the fields when they undergo reflection. Any ordinary text on E&M or optics will show you the equations and the correct sketches.

You are obviously still confusing phasors and fields. More FFP.

But on the other hand many of those theories have been tested
over and over again in all those years. If they pass the continued
test of time, I trust them more than I do bafflegab that usually
breaks these fairly well proven theories with no prior testing done
of the new theories.
I have nothing against trying new ideas, but they should at
least be tested and proven in the real world before they are
unleashed as "fact", or that I need to "recognize" something
that is obviously not the case, already proven through years of
repeated testing.
I've told Art many times... If you build it and it works, they will
come. He refuses.
When a person proclaims that they have a new theory which will
likely break the laws of older proven theory, it's that persons
obligation to prove his case, not the other way around.
And to do that requires getting off ones rear to build and test
the real deal, in the real world and letting the chips fall where
they may.
Art claims to have an 18 ft antenna for 160m on his tower,
but on the other hand he says he does not operate.
So how is he going to test it?
And if it's going to be a fair test, he needs a reference antenna.
If I claimed to have a small antenna that was equal in efficiency
to a full size antenna, I would A/B compare it to a full size
antenna.
If the chips fell in an undesirable manner, I would scrap the
thing, and move on to something else.
It's not like it would be the end of the world.
Art never gets this far. So due to a lack of actual testing, it's
like a dog chasing it's tail, while barking at the moon at the
same time.
I'm all for new ideas, and I surely know that in the history of
the world, people will likely see things much differently 200
years from now, than they do today.
That's a given..
All I'm saying is... Don't feed me a turd and call it steak,
without tasting it first. I can smell the difference in most

cases just from my own prior experiences.
If I thought a 18 ft element could equal a full size element
on 160m, you can bet I would already have one in the air.
But I know just from prior testing with just half size dipoles
using efficient Hi-Q loading coils at optimum locations, that
even they couldn't quite match up. I had to go to a "Z" dipole
to get close to full size efficiency.
So when I hear stories of small radiators wound with thin
22 gauge wire in a "to me" perverted contra wound method,
and this is supposed to be the answer to all our prayers,
please excuse me if I don't rush out to nominate Art for the
Nobel prize in physics without a little real world
demonstration. Using a real full size antenna to compare
it with would be nice.
I would expect no less from even an alien if he promised a
free lunch deal like that. Or myself for that matter.

You are correct to say that education has nothing to do with IQ. Faraday had little formal training, yet his arduous work is now exalted by naming one of the basic electromagnetic laws after him. But I take issue with the idea that you can't actually know anything at all. For instance, electrodynamic theory was developed 150 years ago, and the KNOWN successful results of that are numerous.

Newtonian mechanics held up well for hundreds of years. A whole industrial revolution was built on it. Yet some pesky observations by Michelson and Morley regarding the invariant speed of light found it wanting. Relativistic mechanics subsumed Newtonian mechanics, but Einstein didn't invalidate Newton. I believe the mathematical term "embedding" applies.

I am currently re-studying the original theory of Maxwell, et. al., with the intent of finding some chink in the armor. Tesla reported longitudinal electromagnetic wave phenomena, which contradicts the now-standard theory that EM waves can ONLY be transversal. Using Maxwell's original quaternion equations, before Heviside simplified them into the now-standard vector form, one can derive longitudinal wave components. If those exist, does that prove you don't know how to operate a ham radio? No, it just means you're radiating something in addition to what you expect.

You CAN know something and apply it. You just need to realize that what you know isn't complete, and never can be.

My comment concerned a mobile antenna coupling into nearby conductors.

Are you saying that this is the basis for increased gain from your 160-m, gaussian, compact, full-wave, tank circuit, tilted antenna in equilibrium?

Rewritten to clarify for "art"

Are you saying that coupling from your 160-m, gaussian, compact, full-wave, tank circuit, tilted antenna in equilibrium into randomly located conductors near the transmit antenna is the basis for increased gain from that antenna?

Such random couplings ARE the reason for the increased signals you mentioned in your earlier statement, "You see this effect in a mobile when the audio increases as you drive by power lines and the like," and it appears you are claiming that effect to explain the performance of your 160-m, gaussian, etc, etc antenna in equilibrium.

Please explain.

Tesla made a lot of claims to try to get money from investors. There is no evidence to support his claims of longitudinal electromagnetic waves. What kind of detector did he use? In the century or so since then, why has nobody re-discovered these waves?

You can determine the probability these waves exist with very simple logic.

The range equations for radar and deep space communication are very well established, and the radiated energy is well understood. In order to make progress on discovering longitudinal waves, you have to find some anomaly. If you could show some error in the equations where power was missing, you might be on to something. But first you have to show there really is an anomaly.

If these waves exist, where does the power come from and where does it go? What mechanism determines how the power is split between normal EM waves and longitudinal waves?

You can measure power very accurately. Signal to noise ratio is one of the most crucial parameters in satellite communication. If there were any anomalies in the range equations, someone would have discovered them long ago. And Roy would have updated his code.

You can bet on that!

The chink is provided by Gauss.Adding a time varient to his law of statics brings you to
Maxwells law Holding on to the equilibrium underpinnings you may then insert a radiator that also is in equilibrium i.e. a full wave length. Now you are equipped to insert same into a antenna program to determine shape ,size,elevation e.t.c for maximum horizontal gain. Maxwells law will then show that to meet this requirement is for the radiator to not be parallel to the ground surface but tipped to an angle. This angle is the summation of the curl vector and others that are entailed.Gauss following from the Newtonian aproach of equilibrium provides a pasaage of knoweledge that was not available in the blank statements of Maxwell.
All this provides a picture which equals a thousand words and a sound basis to build upon.
The understanding of this aproach has been stalled with this newsgroup on the basis of transformation of static field to a dynamic field is illegal, regardless of the math proving otherwise! Facts are stranger than the fiction of this group.
Have fun with your studies.

Roy's program is nothing more than a calculator.
It is not equipped with computor analytical skills such as an
optimizer where the computor searches for possible changes to the
imput to determine maximum required results .
As a calculator you insert the math question and the calculator
provides the result
A computor optimizer does exactly what the title suggests, it works
for you in search of a better arrangement that you supplied so you may
determine an optimum solution for the inputted request. None tell you
that thematerial used must be diamagnetic so just use aluminum or
copper
and you will be O.K. As far as purchasing a computor program there are
choices out there that are not so basic.

Hi Lee,

I presume you mean by maploops, those that are only a meter or so in diameter. You need a larger loop for 80M. A simple one turn with plenty of surface area and low Ohmic contacts is preferred as anything more complex invites massive loss.

The law with small antennas is their Radiation Resistance in relation to their Ohmic Resistance. Most would grab some #12 wire and shrug it off without a thought. That lack of thought generates calories in heat. Some would add wire turns, the proximity of them merely multiplies the heat, not the signal.

Either way the tune up seems great, but the results are miserable (no doubt the source of your statement above). A good low band loop will have a sharp tuning (narrow bandwidth). A poor low band loop will appear to exhibit a great SWR for a broad bandwidth, You can test this yourself with almost no effort at all.

Let's take that one meter diameter loop that is available from several commercial outlets, and instead build it your self with house wire (#12). The Radiation Resistance in the 80M band will be 528 millionths of an Ohm, Copper loss will be 16 thousandths of an Ohm (not counting skin effect) - we still haven't computed connection issues. Already, your copper loss is thirty times the radiation resistance - I will let you delve into the issues of efficiency.

Doubling that loop diameter will double the copper loss to 32 thousandths of an Ohm, but what happens to Radiation Resistance? It now runs more to 8 thousandths of an Ohm. The ratio has dropped from 30:1 to 4:1 in this doubling of size - even when the resistance of the wire grew, the Radiation Resistance grew faster. Efficiency increases dramatically.

Increase the loop size and use a larger conductor.

No. I have a radio in my Mercedes and I can tune to the local radio
stations for the music.
Yes I have a a motor like the ones used on dishes.I put in on just as
the snow started to fly
and in my haste altered the antenna some what. In the spring I will
correct that plus wire up
the rotator and tilt mechanism. Why all the questions? As one of the
adjudicators on this group
that determine all that is correct and all that is not you have
identified all that I do as a failure so why the pursuit?

Gene Fuller wrote:
> The graph is complete nonsense. There is no rotation of the fields when
> they undergo reflection. Any ordinary text on E&M or optics will show
> you the equations and the correct sketches.

Good grief, Gene. There is a 360 degree rotation in the fields
every wavelength. The direction of rotation is associated with
the direction of travel of the wave and is displayed by EZNEC
when the current phase option is turned on. All you have to
do to see the rotation of the traveling wave is to download
http://www.w5dxp.com/rhombicT.EZ

Those simplified sketches are making you simple-minded.
Assuming you are a member of the IEEE, look up this paper:
"Rotation in electromagnetic field equations". Or Google
"Rotation and the Electromagnetic Field".

"Optics", by Hecht, is one of your ordinary texts. That is
where the material for that graph comes from. The IEEE Dictionary
says: "E and H are the electric and magnetic field vectors in
phasor notation". If that graph is nonsense to you, it is your
fault, not mine.

Hecht says "Optics", 4th edition, page 289, about standing waves:

"The composite disturbance is then:

E = Eo[sin(kx+wt) + sin(kx-wt)]

Applying the identity:

sin A + sin B = 2 sin 1/2(A+B)*cos 1/2(A-B)

yields:

E(x,t) = 2*Eo*sin(kx)*cos(wt)"

"This is the equation for a STANDING or STATIONARY WAVE, as opposed
to a traveling wave. Its profile does not move through space; it is
clearly not of the form Func(x +/- vt)."

"... a phasor rotating counterclockwise at a rate omega is equivalent
to a wave traveling to the left (decreasing x), and similarly, one
rotating clockwise corresponds to a wave traveling to the right
(increasing x)."

Hecht uses phasors to represent EM waves all through his book.
He explains the standing wave E-field based on the two traveling

waves, E1-field and E2-field, thusly:

"The resultant phasor is E1 + E2 = E ... Keeping the two [traveling wave] phasors tip-to-tail and having E1 rotate counterclockwise as E2 rotates (at the same rate) clockwise, generates E [total] as a function of 't'."

[Standing wave phase] "doesn't rotate at all, and the resultant wave it represents doesn't progress through space - its a standing wave."

Traveling wave phase rotates. Standing wave phase doesn't.

Speaking of "... net transfer of energy, for the pure standing wave there is none."

The forward wave and reflected wave E-field and H-field vectors are represented by phasors just as indicated in the IEEE Dictionary. One is rotating clockwise and the other is rotating counterclockwise. The Poynting vector for a pure standing wave is equal to zero just as illustrated in my graph at: http://www.w5dxp.com/EHSuper.JPG Given those boundary conditions and solving for the angle between the standing wave E-field and H-field yields 0 or 180 degrees.

Are you really more interested in presenting false information and saving face than you are in valid technical facts?

Probably the wave energy that you say never existed.
But you have never provided an example of waves
that can exist without energy.

Set the FSU flash example to 180 degrees out of
phase and please explain conceptually where the
energy in those two waves goes when they
superpose to zero in a transmission line.

So unless somebody can point to the energy that is "in" waves which don't exist, then I will have to stick with the idea that there is no energy to be associated with waves that don't exist. To me it is the only logical way to look at it, even though I may be subject to abuse from crackpots. ;-)

This is not rocket science. If the energy is being used to
transform impedances, it is obviously unavailable to be lost
as radiation. If all the forward energy is radiated by the
antenna, there exists no impedance transformation in the
transmission line. A highly technical quote must be needed:

"You can't have your energy cake and eat it too." :-)

Sure, assuming energy is being "used" to perform an operation in which
no work is done. You'll need to prove the first part of the sentence
in order to show the second part to be true.

Jim, here is the s-parameter equation for the waves that
you assert don't exist.

b1 = s11*a1 + s12*a2 = 0

s11*a1 is not zero. s12*a2 is not zero. How you can assert
that they don't exist is really strange. Not only do they
exist but the HP apnote 95-1 even tells us that the power
associated with them is |s11*a1|^2 and |s12*a2|^2. You will
find that the powers obey the power density (irradiance)
equation from the field of optical physics.

Cecil,
Just a small question.
Do you include in your analysis of E and H waves
the effect of the field produced by a diamagnetic field produced by
current flow in the material, where the field has a tendency to be at
right angles? This is what PROF Hately was looking to do on his EH
invention without understanding the importance of the material used in
generating the fields in question.
Best regards
Art Unwin KB9MZ...xg

I'll be the first to admit there doesn't appear to be much probability for longitudinal waves, since there seems to be no convincing empirical evidence. But, as with Michelson and Morley, who LOGICALLY thought that light should travel at a slower speed against the aether, maybe we just haven't been doing the right observation. Current theory says longitudinal waves can't happen, so nobody seriously looks for them or thinks to attribute any potential anomaly to them. We might have a case of circular reasoning. Besides, practical antennas are designed for transverse far-fields, so I don't expect they would produce much in the way of longitudinal waves, which may be a near-field phenomena.

The quaternion development of EM theory implies that charge divergence is one source of longitudinal waves. That happens along the axis of antenna conductors, but I doubt the efficiency of conversion, assuming there is any, would be very high. Another theoretical source of longitudinal waves come from high rate of change electric fields. Tesla's inventions exhibited both sources. His pancake coils created high current divergence, albeit in a spiral pattern. And his high voltage spark discharge devices created exceedingly high rates of change of voltage.

Where would the power come from for longitudinal waves? If I can't use regular electricity, I'm holding out for conversion of zero-point energy or direct mass-energy conversion. Yeah, I know, more crackpot long shots.

I'll need something to do in retirement other than the wife's housework. I read that mental challenges help stave off Alzheimer's. You can't beat this for a challenge. Or maybe this falling down this rabbit hole of kookism is the onset of Alzheimer's. Hmm. Hadn't thought of that before.

But when adding vectors as I see it there is no secondary vectors,
which in this case
says both vectors are in phase no less.I thought I would probe a bit
in this long
thread to ascertain where the controversy is. To understand that alone
in the face of thousand postings is a very difficult task indeed.Even
more so for a mechanical engineer
Very best regards

Light does travel at a slower speed against the aether
but relativity changes the length of a second when going
against the aether so it is undetectable.

So you found out that I have a 1/4 wave tank circuit in my
transmitter. Only the MI5 could have known that. Hmmm...

When I drive across a long bridge, I am trusting that
most mechanical engineers don't have a problem with
vectors. :-)

A problem seeking a solution.

I live in a wooded area of the Pacific Northwest with dozens of fir trees of 100 ft or more in height that make wonderful supports for high dipoles and other wire antennas. These particular trees have very few limbs at anything below the 60 ft level so using a crossbow or slingshot for installation is not practical. I have been forced to employ a professional tree climber to install the eyebolts and halyards. Using this system, the antennas can be raised and lowered for maintenance or modification.

This system works fine until our winter storms kick in. Often, during those storms, a tree will lose a limb or two and take the antenna down with it. I am then left with a halyard tied to an insulator 50 ft or more above the ground with no way to get the insulator back down short of hiring another costly climber.

Does anyone have any solutions to this problem?

73,

John

Yeah, used to be that way in California--last earthquake destroyed
that--maybe you heard about it? :-D

Regards,
JS
